

TORUS ACTIONS WHOSE EQUIVARIANT COHOMOLOGY IS COHEN-MACAULAY

OLIVER GOERTSCHES AND DIRK TÖBEN

ABSTRACT. We study Cohen-Macaulay actions, a class of torus actions on manifolds, possibly without fixed points, which generalizes and has analogous properties as equivariantly formal actions. Their equivariant cohomology algebras are computable in the sense that a Chang-Skjelbred Lemma, and its stronger version, the exactness of an Atiyah-Bredon sequence, hold. The main difference is that the fixed point set is replaced by the union of lowest dimensional orbits. We find sufficient conditions for the Cohen-Macaulay property such as the existence of an invariant Morse-Bott function whose critical set is the union of lowest dimensional orbits, or open-face-acyclicity of the orbit space. Specializing to the case of torus manifolds, i.e., $2r$ -dimensional orientable compact manifolds acted on by r -dimensional tori, the latter is similar to a result of Masuda and Panov, and the converse of the result of Bredon that equivariantly formal torus manifolds are open-face-acyclic.

1. INTRODUCTION

In the theory of equivariant cohomology, the class of equivariantly formal actions of a real torus T on a compact manifold M is certainly one of the most intensely studied. On the one hand, it comprises many important examples, such as Hamiltonian torus actions on compact symplectic manifolds, and on the other hand such actions have many beautiful properties, e.g. the equivariant cohomology $H_T^*(M)$ is determined by the 1-skeleton of the action as proven by Chang and Skjelbred [ChSk 1974, Lemma 2.3], and thereby explicitly computable [GKM 1998, Theorem 1.2.2] via what is nowadays called GKM theory, see e.g. [GuZa 2001]. To our knowledge, the only known big classes of actions on manifolds for which the $(S(\mathfrak{t}^*)\text{-algebra structure of the})$ equivariant cohomology is explicitly computable are either equivariantly formal or have only one isotropy type.

A geometric property of equivariantly formal actions is that their minimal strata consist of fixed points. The fixed point set of an action plays an important role in the whole theory, as shown by e.g. the famous localization theorems. A basic example of its relevance is that it encodes the rank of $H_T^*(M)$ as a module over $S(\mathfrak{t}^*)$.

The motivating question for our work was the following: *Is there a suitable generalization of equivariant formality that also covers actions without fixed points?*

From the point of view of computability of $H_T^*(M)$, the answer to this question is implicit in the proof of the exactness of the so-called Atiyah-Bredon sequence [Bre 1974] (Theorem 4.4, see also [FrPu 2003]), which can be regarded as an extension of the Chang-Skjelbred Lemma; the relevant property of $H_T^*(M)$ for the proof is not that it is a free module, but that it is a Cohen-Macaulay module of Krull dimension $\dim T$.

In Section 6 we give the

Definition. The T -action is *Cohen-Macaulay* if $H_T^*(M)$ is a Cohen-Macaulay module over $S(\mathfrak{t}^*)$.

The Cohen-Macaulay property was used as a tool in various papers on equivariant cohomology. The purpose of this work is to justify why it is the appropriate notion for answering the above question. The central role of the fixed point set will be seen to be assumed by the union of lowest dimensional orbits.

Let b be the smallest occurring orbit dimension. Similarly to the equivariantly formal case [Bre 1974, FrPu 2007], there is an Atiyah-Bredon sequence, but with the fixed point set replaced by the union M_b of b -dimensional orbits, whose exactness is equivalent to Cohen-Macaulayness (Theorem 6.2):

Theorem. *The T -action on M is Cohen-Macaulay if and only if the sequence*

$$0 \rightarrow H_T^*(M) \rightarrow H_T^*(M_b) \rightarrow H_T^*(M_{b+1}, M_b) \rightarrow \dots \rightarrow H_T^*(M, M_{\text{sing}}) \rightarrow 0$$

is exact.

The notion of Cohen-Macaulay action encompasses both equivariantly formal actions and actions with only one isotropy type, including locally free actions. Namely, if the action is equivariantly formal, i.e., $H_T^*(M)$ is a free module, $H_T^*(M)$ is Cohen-Macaulay of maximal Krull dimension $\dim T$, and if the action is locally free it is Cohen-Macaulay of Krull dimension 0. Effective cohomogeneity-one actions are examples of Cohen-Macaulay actions of Krull dimension 1, see Example 6.5. To show that there are many more interesting examples of Cohen-Macaulay actions,

we relax well-known sufficient conditions for equivariant formality in a way that we retain the Cohen-Macaulay property: (Theorem 7.1)

Theorem. *If the action admits a T -invariant Morse-Bott function with critical set M_b , then the action is Cohen-Macaulay.*

and (Theorem 8.1)

Theorem. *If the T -manifold M admits a T -invariant disk bundle decomposition satisfying the properties of Theorem 8.1, then the action is Cohen-Macaulay.*

In every case, the philosophy is to replace the fixed point set by the union of lowest dimensional orbits.

The second half of the paper is dedicated to the question whether it is possible to give conditions on the orbit space of the action that imply that the action is Cohen-Macaulay. In Section 9, we prove an algebraic characterization of injectivity of the restriction map $H_T^*(M) \rightarrow H_T^*(B)$, where B is the bottom stratum of the action, i.e., the union of the minimal strata. This yields as a corollary the geometric statement (Theorem 9.6)

Theorem. *If the orbit space of the T -action is almost open-face-acyclic, then $H_T^*(M) \rightarrow H_T^*(B)$ is injective.*

Masuda and Panov [MaPa 2006] proved that a torus manifold, i.e., an orientable compact $2 \dim T$ -dimensional manifold with fixed points, is equivariantly formal with respect to $\mathbb{Z}$ -coefficients if and only if it is locally standard and its orbit space is closed-face-acyclic. In Section 10 we show (Corollary 10.7, Theorem 10.24)

Theorem. *If T acts effectively on an orientable compact manifold M with open-face-acyclic orbit space, then $\dim M = 2 \dim T - b$ and the action is Cohen-Macaulay.*

Here b is the lowest occurring orbit dimension. To a large extent, our proof uses the ideas of Masuda and Panov; however, there are several differences: Most importantly, several special features such as the so-called canonical models [MaPa 2006, Section 4.2], see Davis and Januszkiewicz [DaJa 1991, Section 1.5], or the equivalent characterization of equivariant formality via $H^{odd}(M) = 0$, are not available in our setting. Our chain of arguments instead relies on the fact that equivariant injectivity holds a priori by the results in Section 9, and various other modifications.

Our result states that actions on $2 \dim T$ -dimensional orientable compact manifolds with open-face-acyclic orbit space are equivariantly formal. The converse of this statement was proven by Bredon [Bre 1974, Corollary 3]; we therefore obtain (Theorem 10.25):

Theorem. *A T -action on an orientable compact manifold M with $\dim M = 2 \dim T$ is equivariantly formal if and only if its orbit space is open-face-acyclic.*

Acknowledgements. We are grateful to Sönke Rollenske for various discussions on Cohen-Macaulay modules, and useful comments on a preliminary version of this paper. We wish to thank Matthias Franz and Volker Puppe for bringing to our attention Proposition 5.1 of their paper [FrPu 2003] and the important connection between Cohen-Macaulay and equivariantly formal actions described in Remark 6.3. These two points were independently noticed by the referee, whom we thank for his careful reading resulting in several improvements of the paper.

2. PRELIMINARIES

Throughout this paper, $T = (S^1)^r$ will denote an r -dimensional real torus. We will use several cohomology theories, always with $\mathbb{R}$ as coefficient ring. All of them are defined for arbitrary (T) -spaces, but have an equivalent description in the case of a differentiable manifold (with a differentiable T -action). H^* denotes singular (or deRham) cohomology. For a T -space X , $H_T^*(X)$ denotes equivariant cohomology of the T -action, i.e., the cohomology of the Borel construction $X_T = X \times_T ET$ [BBFMP 1960, Hsi 1975]. In the differentiable case this coincides with equivariant de Rham cohomology, see e.g. [GuSt 1999]. We will use the Cartan model $H_T^*(X) = H(S(\mathfrak{t}^*) \otimes \Omega(X)^T, d_T)$, where $S(\mathfrak{t}^*)$ is the symmetric algebra on the dual of the Lie algebra $\mathfrak{t}$ of T , $\Omega(X)^T$ consists of the T -invariant differential forms on X , and d_T is the equivariant differential.

Given a T -action on an arbitrary space X , the basic cohomology $H_{bas}^*(X)$ will be understood as the singular cohomology of the quotient X/T . In the differentiable case this coincides with the usual definition of basic cohomology [Mic 2008, Theorem 30.36]: a differential form ω is *basic* if it is horizontal, i.e., the contractions with the T -fundamental vector fields vanish, and T -invariant. Then $H_{bas}^*(X) = H(\Omega_{bas}^*(X), d)$, where $(\Omega_{bas}^*(X), d)$ is the complex of basic forms, with d the restriction of the usual differential.

The projection $X_T \rightarrow X/T$ naturally induces a map

$$(2.1) \quad H_{bas}^*(X) \rightarrow H_T^*(X),$$

which in the differentiable case can also be seen to be induced by the inclusion of complexes $(\Omega_{bas}^*(X), d) \rightarrow (S(\mathfrak{t}^*) \otimes \Omega(X)^T, d_T)$. Note that in general (2.1) is not injective, see e.g. [GGK 2002, Example C.18].

There are also relative and compactly supported versions of equivariant and basic cohomology, where the latter will be denoted by an additional index, e.g. $H_{T,c}^*$ for compactly supported equivariant cohomology [GuSt 1999, Section 11.1].

In case T acts locally freely on an orientable manifold M , then M/T is an orientable orbifold and hence [Sat 1956] there is Poincaré duality for basic cohomology: $H_{bas}^*(M) = H^*(M/T) \cong H_c^{\dim M/T-*}(M/T) = H_{bas,c}^{\dim M/T-*}(M)$.

For a T -action on a manifold M and any subspace $\mathfrak{k} \subset \mathfrak{t}$, let $M^{\mathfrak{k}}$ be the common zero set of all fundamental vector fields induced by $\mathfrak{k}$. In other words, $M^{\mathfrak{k}}$ is the fixed point set of the action of the connected Lie subgroup of T with Lie algebra $\mathfrak{k}$. For $p \in M$, let M^p be the connected component of $M^{\mathfrak{t}_p}$ that contains p . A point is *regular* if its isotropy algebra is minimal among all isotropy algebras, and nonregular points are called *singular*. The regular set of the T -action on M is denoted M_{reg} , and the singular set M_{sing} . The respective regular and singular sets of the T -action on M^p are $M_{reg}^p = \{q \in M^p \mid \mathfrak{t}_q = \mathfrak{t}_p\}$ and $M_{sing}^p = M^p \setminus M_{reg}^p$. The M^p are partially ordered by inclusion. The minimal elements M^p with respect to this ordering are exactly those with $M^p = M_{reg}^p$. By definition, the *bottom stratum* B of the action is the union of those minimal elements:

$$B = \{p \in M \mid M^p = M_{reg}^p\}.$$

(Strictly speaking, one should refer to B as the infinitesimal bottom stratum, as for the definition of regularity of a point we only consider its isotropy algebra instead of its isotropy group.) The set of fixed points $M^{\mathfrak{t}}$ is contained in B .

For $i \geq 0$, let M_i be the union of orbits of dimension $\leq i$. Clearly,

$$M_i = \bigcup_{p \in M: \dim \mathfrak{t}_p \geq r-i} M^p.$$

Furthermore, we define $M_{(i)} = M_i \setminus M_{i-1}$ to be the union of orbits of dimension equal to i . The $M_{(i)}$ are disjoint unions of submanifolds of type M_{reg}^p . In general, M_i is not a submanifold of M , but still it is an equivariant strong deformation retract of some neighborhood in M (or M_{i+1}). Of importance will be the cohomology of the pair (M_i, M_{i-1}) . For later use, we note that

$$H_{bas}^*(M_i, M_{i-1}) = H_{bas,c}^*(M_{(i)}) = H_c^*(M_{(i)}/T)$$

and

$$H_T^*(M_i, M_{i-1}) = H_{T,c}^*(M_{(i)}).$$

3. GENERAL LEMMATA

In this section, we collect some more or less well-known lemmata on equivariant cohomology. If A is a finitely generated graded $S(\mathfrak{t}^*)$ -module, we define the *support* of A as in [GuSt 1999, Section 11.3] to be the set of complex zeroes of the annihilator ideal of A :

$$\text{supp } A = \{x \in \mathfrak{t} \otimes \mathbb{C} \mid f(x) = 0 \text{ for all } f \in S(\mathfrak{t}^*) \text{ with } fA = 0\}.$$

Because A is graded, the annihilator ideal is a graded ideal, and $\text{supp } A$ is a conic subvariety of $\mathfrak{t} \otimes \mathbb{C}$, i.e., for $x \in \text{supp } A$ and $\lambda \in \mathbb{C}$ we have $\lambda x \in \text{supp } A$. For an element $\alpha \in A$, we define the support of α to be the support of the submodule of A generated by α : $\text{supp } \alpha = \text{supp } S(\mathfrak{t}^*)\alpha$. Clearly, for every $\alpha \in A$ we have $\text{supp } \alpha \subset \text{supp } A$.

Lemma 3.1. *Let a torus T act on a manifold M . If $K \subset T$ is any (not necessarily closed) Lie subgroup that acts trivially on M and $K' \subset T$ a subtorus of T such that $\mathfrak{k} \oplus \mathfrak{k}' = \mathfrak{t}$, then*

$$H_T^*(M) = S(\mathfrak{k}^*) \otimes_{\mathbb{R}} H_{K'}^*(M)$$

as an $S(\mathfrak{t}^*) = S(\mathfrak{k}^*) \otimes S(\mathfrak{k}'^*)$ -algebra.

Proof. We have $S(\mathfrak{t}^*) \otimes \Omega(M)^T = S(\mathfrak{k}^*) \otimes (S(\mathfrak{k}'^*) \otimes \Omega(M)^{K'})$. The equivariant differential d_T leaves the space $S(\mathfrak{k}^*) \otimes \Omega(M)^{K'}$ invariant and is zero on $S(\mathfrak{k}^*)$. Thus, $H_T^*(M) = S(\mathfrak{k}^*) \otimes H^*(S(\mathfrak{k}'^*) \otimes \Omega(M)^{K'}, d_{K'}) = S(\mathfrak{k}^*) \otimes H_{K'}^*(M)$. $\square$

Lemma 3.2. *Let T act on a compact manifold M and $\mathfrak{k} \subset \mathfrak{t}$ be any subspace. Then the kernel of the restriction map $H_T^*(M) \rightarrow H_T^*(M^{\mathfrak{k}})$ is given by $\{\alpha \mid \mathfrak{k} \otimes \mathbb{C} \not\subset \text{supp } \alpha\}$.*

Proof. Note that $M^{\mathfrak{k}}$ is a closed T -invariant submanifold of M . By [GuSt 1999, Theorem 11.4.2] the kernel of the restriction map i^* has support in the union of those subalgebras that occur as isotropy algebras in $M \setminus M^{\mathfrak{k}}$, i.e.

$$\text{supp } \ker i^* \subset \bigcup_{\mathfrak{h} \text{ isotropy algebra, } \mathfrak{k} \not\subset \mathfrak{h}} \mathfrak{h} \otimes \mathbb{C}.$$

Thus, $\mathfrak{k} \otimes \mathbb{C} \not\subset \text{supp } \ker i^*$. Since for any $\alpha \in \ker i^*$, we have $\text{supp } \alpha \subset \text{supp } \ker i^*$, we obtain $\mathfrak{k} \otimes \mathbb{C} \not\subset \text{supp } \alpha$.

Conversely, let $\alpha \notin \ker i^*$ and choose a subtorus $K' \subset T$ such that $\mathfrak{t} = \mathfrak{k} \oplus \mathfrak{k}'$. Then, $0 \neq i^*\alpha \in H_T^*(M^{\mathfrak{k}}) = S(\mathfrak{k}^*) \otimes H_{K'}^*(M^{\mathfrak{k}})$ by the previous lemma, so $\mathfrak{k} \otimes \mathbb{C} \subset \text{supp } i^*\alpha \subset \text{supp } \alpha$. $\square$

Proposition 3.3. *Let a torus T act on a manifold M . Then the following properties are equivalent:*

- (1) *The action is locally free.*
- (2) $H_T^k(M) = 0$ for large k .
- (3) $\text{supp } H_T^*(M) = \{0\}$.
- (4) *The support of $1 \in H_T^*(M)$ is $\{0\}$.*

Proof. We show $(1) \Rightarrow (2) \Rightarrow (3) \Rightarrow (4) \Rightarrow (1)$. If the action is locally free, $H_T^*(M) = H^*(M/T)$ (this is standard for free actions, but also true for only locally free actions because we are using real coefficients, see e.g. Section C.2 of [GGK 2002]), so (1) implies (2).

Assuming (2), there is some $N > 0$ such that any closed equivariant differential form of degree at least N is exact. Thus, writing $S(\mathfrak{t}^*) = \mathbb{R}[u_1, \dots, u_n]$, it follows that for any i some power of u_i annihilates $H_T^*(M)$. Therefore the common zero set of the polynomials that annihilate $H_T^*(M)$ consists only of the element 0, hence (3).

It is clear that (3) implies (4), so it remains to show that (4) implies (1). Clearly, the complexification of every isotropy algebra $\mathfrak{k}$ is contained in the support of 1, because 1 is not in the kernel of $H_T^*(M) \rightarrow H_T^*(M^{\mathfrak{k}})$. Thus, if the support of 1 is $\{0\}$, the action is locally free. $\square$

4. EQUIVARIANT FORMALITY

The T -action on M is equivariantly formal in the sense of [GKM 1998] if the cohomology spectral sequence associated with the fibration $M \times_T ET \rightarrow BT$ collapses at E_2 . The following are well-known equivalent characterizations of equivariant formality:

- (1) $H_T^*(M)$ is free as an $S(\mathfrak{t}^*)$ -module [AlPu 1993, Corollary 4.2.3].
- (2) $\dim H^*(M^T) = \dim H^*(M)$ [Hsi 1975, Corollary IV.2]. The inequality $\leq$ is true for any T -action.

An important sufficient condition for equivariant formality is $H^{\text{odd}}(M) = 0$, see [GuSt 1999, Theorem 6.5.3].

Also the following proposition is fairly standard. One way to prove it is as an application of characterization (2) above, see e.g. the proof of the Main Lemma in [Bre 1974]; a proof using (1) is given in [Bri 2000, Lemma 2].

Proposition 4.1. *If the T -action on M is equivariantly formal, then for any subtorus $K \subset T$, the T/K -action on $M^{\mathfrak{k}}$ is equivariantly formal.*

The next lemma can be proven as a direct application of characterization (2) above.

Lemma 4.2. *A T -action on M is equivariantly formal if and only if the T -action on each connected component of M is equivariantly formal.*

The following corollary appears (with a different proof) as Theorem 11.6.1 in [GuSt 1999], and as Proposition C.28 in [GGK 2002].

Corollary 4.3. *If the T -action on M is equivariantly formal and $K \subset M$ is any subtorus, each connected component of $M^{\mathfrak{k}}$ contains a T -fixed point. In other words: the bottom stratum of an equivariantly formal action is equal to the set of fixed points.*

Proof. This follows from Proposition 4.1 and Lemma 4.2 because every equivariantly formal action has a fixed point. $\square$

The relevance of the notion of equivariant formality emerges from the fact that the equivariant cohomology of spaces satisfying this condition is (relatively) easy to compute, thanks to the exact sequence

$$0 \rightarrow H_T^*(M) \rightarrow H_T^*(M_0) \xrightarrow{\partial} H_T^*(M_1, M_0).$$

Here, ∂ is the boundary operator in the long exact sequence of the pair (M_1, M_0) . Injectivity of $H_T^*(M) \rightarrow H_T^*(M_0)$ follows because the kernel of this map is the module of torsion elements [GuSt 1999, Theorem 11.4.4] and $H_T^*(M)$ is torsion-free¹. Exactness at $H_T^*(M_0)$ is the so-called Chang-Skjelbred Lemma [ChSk 1974, Lemma 2.3], see also [GuSt 1999, Section 11.5].

The following characterization of equivariant formality is an extension of the exact sequence above.

Theorem 4.4 ([Bre 1974], [FrPu 2007]). *The T -action on M is equivariantly formal if and only if the sequence*

$$0 \rightarrow H_T^*(M) \rightarrow H_T^*(M_0) \rightarrow H_T^*(M_1, M_0) \rightarrow \dots \rightarrow H_T^*(M, M_{\text{sing}}) \rightarrow 0$$

is exact.

In this sequence, the maps $H_T^*(M_i, M_{i-1}) \rightarrow H_T^*(M_{i+1}, M_i)$ are the boundary operators of the triples (M_{i+1}, M_i, M_{i-1}) . Exactness of the sequence under the condition of equivariant formality was proven by Bredon [Bre 1974, Main Lemma], adapting an analogous result of Atiyah in equivariant K -theory [Ati 1974, Lecture 7]. Following Franz and Puppe, we will therefore refer to this sequence as the Atiyah-Bredon sequence. The converse direction is due to Franz and Puppe [FrPu 2007, Theorem 1.1]. Note that because we are using real coefficients we do not need any assumptions on the connectedness of isotropy groups, as is pointed out in Remark 1.2 of [FrPu 2007]. For a version of the result of Atiyah and Bredon for other coefficients, see [FrPu 2003].

The following proposition shows that exactness of the Atiyah-Bredon sequence at $H_T^*(M)$ and $H_T^*(M_0)$ is implied by exactness of the rest of the sequence.

Proposition 4.5. *Let H^* denote either equivariant or basic cohomology. If for some i , the truncated Atiyah-Bredon sequence*

$$H^*(M_i) \rightarrow H^*(M_{i+1}, M_i) \rightarrow \dots \rightarrow H^*(M, M_{\text{sing}}) \rightarrow 0$$

is exact, then also

$$0 \rightarrow H^*(M) \rightarrow H^*(M_i) \rightarrow H^*(M_{i+1}, M_i) \rightarrow \dots \rightarrow H^*(M, M_{\text{sing}}) \rightarrow 0.$$

One way to see this is to regard the maps in the sequence as differentials in the spectral sequence associated to the filtration $M_i \subset M_{i+1} \subset \dots \subset M_{r-1} \subset M_r$. The assumption implies that this spectral sequence collapses, and because it converges to $H^*(M)$, the statement follows. This argument was used in [Bre 1974, p. 846]. It can also be proven by hand: for the injectivity of $H^*(M) \rightarrow H^*(M_i)$, a straightforward diagram chase shows that for every $j \geq i$, we have $\ker(H^*(M) \rightarrow H^*(M_j)) = \ker(H^*(M) \rightarrow H^*(M_{j+1}))$. For exactness at $H^*(M_i)$, another diagram chase proves that for every $j \geq i+1$, the image of $H^*(M_j) \rightarrow H^*(M_i)$ equals the image of $H^*(M_{j+1}) \rightarrow H^*(M_i)$.

¹This condition is not equivalent to equivariant formality; see [FrPu 2008] for an example.

5. COHEN-MACAULAY MODULES OVER GRADED RINGS

In the literature, the Cohen-Macaulay property usually is considered for modules over Noetherian (local) rings. In our situation, it is natural to consider the graded version of this concept.

Using the language of e.g. [BrHe 1993, Section 1.5], a graded ring R (graded over the integers) is $\ast$ local if it has a unique $\ast$ maximal ideal, where a $\ast$ maximal ideal is a graded ideal $\mathfrak{m} \neq R$ which is maximal among the graded ideals. Thus, $S(\mathfrak{t}^\ast)$ is a Noetherian graded $\ast$ local ring. Note that in general a $\ast$ maximal ideal is not necessarily maximal.

Let R be a Noetherian graded $\ast$ local ring, with $\ast$ maximal ideal $\mathfrak{m}$. Then the *depth* of a finitely generated graded module A over R is defined as the length of a maximal A -regular sequence in $\mathfrak{m}$:

$$\text{depth } A = \text{grade}(\mathfrak{m}, A).$$

The *Krull dimension* of A , denoted $\dim A$, is defined as the Krull dimension of the ring $R/\text{Ann}(A)$, where $\text{Ann}(A) = \{r \in R \mid rA = 0\}$, i.e., the supremum of the lengths of chains of prime ideals in R containing $\text{Ann}(A)$.

Definition 5.1. A finitely generated graded module A over a Noetherian graded $\ast$ local ring R is *Cohen-Macaulay* if $\text{depth } A = \dim A$.

Instead of working with the graded notions, we could equally well localize everything at the $\ast$ maximal ideal (as e.g. Franz and Puppe [FrPu 2003] do it in their proof of the exactness of the Atiyah-Bredon sequence for other coefficients), because of the following proposition:

Proposition 5.2. *Let A be a finitely generated graded module over a Noetherian graded $\ast$ local ring R with $\ast$ maximal ideal $\mathfrak{m}$ such that $R/\mathfrak{m}$ is a field (e.g. $R = S(\mathfrak{t}^\ast)$). Then the following conditions are equivalent:*

- (1) A is Cohen-Macaulay over R
- (2) $A_{\mathfrak{m}}$ is Cohen-Macaulay over the local ring $R_{\mathfrak{m}}$
- (3) $A_{\mathfrak{m}'}$ is Cohen-Macaulay over the local ring $R_{\mathfrak{m}'}$ for all (not necessarily graded) maximal ideals $\mathfrak{m}' \subset R$.

If these conditions are satisfied, then the Krull dimensions of the R -module A and the $R_{\mathfrak{m}}$ -module $A_{\mathfrak{m}}$ coincide.

Proof. The equivalence of (2) and (3) is [BrHe 1993, Exercise 2.1.27.(c)] and valid without the additional assumption that $R/\mathfrak{m}$ is a field; note that there, Cohen-Macaulay modules (over arbitrary Noetherian rings) are defined via condition (3) of this proposition.

We only explain the equivalence of (1) and (2). In fact, we show that the depths of A and $A_{\mathfrak{m}}$ and the Krull dimensions of A and $A_{\mathfrak{m}}$ coincide without using the Cohen-Macaulay property. We have $\text{depth } A = \text{grade}(\mathfrak{m}, A) = \text{depth } A_{\mathfrak{m}}$ by [BrHe 1993, Prop. 1.5.15.(e)]. For the equality of the dimensions, note that $\dim A = \sup_{\mathfrak{m}'} \dim A_{\mathfrak{m}'}$, where $\mathfrak{m}'$ varies over all maximal ideals in R , so obviously $\dim A_{\mathfrak{m}} \leq \dim A$. For the other inequality we use that if $\mathfrak{m}' \neq \mathfrak{m}$ is another maximal ideal, then by [BrHe 1993, Theorem 1.5.8.(b)] the largest graded prime ideal $\mathfrak{p} \subset \mathfrak{m}'$ satisfies $\dim A_{\mathfrak{m}'} = \dim A_{\mathfrak{p}} + 1$. Because of the assumption that $R/\mathfrak{m}$ is a field, $\mathfrak{p}$ is properly contained in the $\ast$ maximal ideal $\mathfrak{m}$, so $\dim A_{\mathfrak{p}} < \dim A_{\mathfrak{m}}$, and hence $\dim A_{\mathfrak{m}'} \leq \dim A_{\mathfrak{m}}$. $\square$

The proof implies that for a finitely generated module over an arbitrary Noetherian graded $\ast$ -local ring R , the inequality $\text{depth } A_{\mathfrak{m}} \leq \dim A_{\mathfrak{m}}$ for the localized module $A_{\mathfrak{m}}$ over $R_{\mathfrak{m}}$ translates to the corresponding one for A : if $A \neq 0$, then

$$\text{depth } A \leq \dim A.$$

For later use, we collect some well-known lemmata on Cohen-Macaulay modules. The first two, which describe how depth and the Cohen-Macaulay property behave with respect to short exact sequences, will be crucial for all our proofs that the equivariant cohomology of actions with certain properties is Cohen-Macaulay.

Lemma 5.3 ([BrHe 1993, Proposition 1.2.9]). *Let $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$ be an exact sequence of finitely generated graded modules over a Noetherian graded $\ast$ -local ring R . Then*

- (1) $\text{depth } A \geq \min\{\text{depth } B, \text{depth } C + 1\}$
- (2) $\text{depth } B \geq \min\{\text{depth } A, \text{depth } C\}$
- (3) $\text{depth } C \geq \min\{\text{depth } A - 1, \text{depth } B\}$

Lemma 5.4. *Let $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$ be an exact sequence of finitely generated graded modules over a Noetherian graded $\ast$ -local ring R . Then the following statements are true:*

- (1) *If A and C are Cohen-Macaulay of the same Krull dimension n , then B is also Cohen-Macaulay of Krull dimension n .*
- (2) *If B and C are Cohen-Macaulay of the same Krull dimension n , then either $A = 0$ or A is also Cohen-Macaulay of Krull dimension n .*

Proof. We have $\dim B = \sup_{\mathfrak{p}} \dim R/\mathfrak{p}$, where the supremum is taken over those prime ideals $\mathfrak{p}$ with $B_{\mathfrak{p}} \neq 0$, see [Ser 2000, Ch. III, B.1]. Thus, Proposition I.4 of [Ser 2000] implies that $\dim B = \max\{\dim A, \dim C\}$ for any short exact sequence of finitely generated R -modules. To see how the depths of the modules relate, use Lemma 5.3: in case (1), it implies that $n \leq \text{depth } B \leq \dim B = n$, since $\text{depth } B \leq \dim B$ in any case. In case (2) and $A \neq 0$, the lemma implies that $n \leq \text{depth } A \leq \dim A \leq n$. $\square$

Remark 5.5. If A and B are Cohen-Macaulay of the same Krull dimension n and $C \neq 0$, then C is not necessarily Cohen-Macaulay of Krull dimension n . For example, consider the short exact sequence $0 \rightarrow \mathbb{R}[t] \xrightarrow{\cdot t} \mathbb{R}[t] \rightarrow \mathbb{R} \rightarrow 0$.

Example 5.6. If a T -action on a compact manifold M and i is such that $M_{i-1} \neq M_i$, then $H_T^*(M_i, M_{i-1})$ is a Cohen-Macaulay module of Krull dimension $r - i$. In fact, if we choose points p_j such that $M_{(i)}$ is the disjoint union of the $M_{reg}^{p_j}$, then

$$H_T^*(M_i, M_{i-1}) = H_{T,c}^*(M_{(i)}) = \bigoplus_j H_{T,c}^*(M_{reg}^{p_j}) = \bigoplus_j H_{bas,c}^*(M_{reg}^{p_j}) \otimes S(\mathfrak{t}_j^*),$$

where $\mathfrak{t}_j$ is the unique isotropy algebra of $M_{reg}^{p_j}$. Thus, $H_T^*(M_i, M_{i-1})$ is the sum of Cohen-Macaulay modules of Krull dimension $r - i$, and Lemma 5.4 implies that it is Cohen-Macaulay of Krull dimension $r - i$ itself.

Lemma 5.7 ([FrPu 2003, Lemma 4.3]). *Let A be a finitely generated module over a Noetherian graded $\ast$ -local ring R . If A is Cohen-Macaulay and $B \subset A$ a non-zero submodule, then $\dim B = \dim A$.*

Proof. We only need to show $\dim B \geq \dim A$. Let $\mathfrak{p} \in \text{Ass}(B)$ be an associated prime ideal of B , i.e., $\mathfrak{p}$ is the annihilator of some element in B . Because $B_{\mathfrak{p}} \neq 0$, we have $\dim B \geq \dim R/\mathfrak{p}$. Furthermore, Proposition 1.2.13. of [BrHe 1993] is true in the graded setting, and hence $\dim R/\mathfrak{p} \geq \text{depth } A = \dim A$. $\square$

6. COHEN-MACAULAY ACTIONS

In this section, we introduce our main object of study. Examining the proof that equivariant formality implies the exactness of the Atiyah-Bredon sequence [Bre 1974] (see also [FrPu 2003]), one sees that the relevant property of $H_T^*(M)$ is not that it is a free $S(\mathfrak{t}^*)$ -module, but that it is a Cohen-Macaulay module of Krull dimension $r = \dim T$.

It is proven in [FrPu 2003, Proposition 5.1] that for any T -action on M the Krull dimension of the $S(\mathfrak{t}^*)$ -module $H_T^*(M)$ equals the dimension of a maximal isotropy algebra (i.e., the Lie algebra of an isotropy group).

Definition 6.1. Let T act on a compact manifold M . We say that the action is *Cohen-Macaulay* if $H_T^*(M)$ is a Cohen-Macaulay module over $S(\mathfrak{t}^*)$.

If b denotes the lowest occurring dimension of a T -orbit, i.e., $M_b \neq \emptyset$ but $M_{b-1} = \emptyset$, then the dimension of a maximal isotropy algebra is $\dim T - b = r - b$. With this definition, Theorem 4.4 is still valid in the sense of the following Theorem.

Theorem 6.2. *Let T act on a compact manifold M , and denote by b the lowest occurring dimension of a T -orbit. Then the following conditions are equivalent:*

- (1) *The action is Cohen-Macaulay*
- (2) *The sequence*

$$0 \rightarrow H_T^*(M) \rightarrow H_T^*(M_b) \rightarrow H_T^*(M_{b+1}, M_b) \rightarrow \dots \rightarrow H_T^*(M, M_{\text{sing}}) \rightarrow 0$$

(which we will refer to as the Atiyah-Bredon sequence) is exact.

Proof. For the proof of (1) $\Rightarrow$ (2), we follow [FrPu 2003] closely. The proof of (2) $\Rightarrow$ (1) naturally reverses the arguments of (1) $\Rightarrow$ (2).

Without loss of generality, we can assume that the action is effective, i.e., $M = M_r$ and $M_{\text{sing}} = M_{r-1}$. For both directions we will use the following consequence of the localization theorem, see [FrPu 2003, Lemma 4.4],

$$(6.1) \quad \dim H_T^*(M, M_j) \leq r - j - 1$$

and the fact that exactness of the Atiyah-Bredon sequence is equivalent to the exactness of the sequences

$$(6.2) \quad 0 \rightarrow H_T^*(M, M_{j-1}) \rightarrow H_T^*(M_j, M_{j-1}) \rightarrow H_T^*(M, M_j) \rightarrow 0$$

for $j \geq b$, see [FrPu 2007, Lemma 4.1].

Assuming the action is Cohen-Macaulay, we prove by induction that (6.2) is exact and that $H_T^*(M, M_j)$ is Cohen-Macaulay of Krull dimension $r - j - 1$. Assume we have shown that $H_T^*(M, M_{j-1})$ is Cohen-Macaulay of Krull dimension $r - j$. For the exactness of (6.2), we show that $H_T^*(M, M_j) \rightarrow H_T^*(M, M_{j-1})$ is the zero map. Since $H_T^*(M, M_{j-1})$ is Cohen-Macaulay of Krull dimension $r - j$, the image of $H_T^*(M, M_j)$ under the map in question is, by Lemma 5.7, either zero or has Krull dimension $r - j$ as well. But on the other hand, (6.1) implies that its Krull dimension is at most $r - j - 1$, hence the image vanishes and (6.2) is exact. Because $\text{depth } H_T^*(M_j, M_{j-1}) = r - j$ by Example 5.6, Lemma 5.3 implies that $\text{depth } H_T^*(M, M_j) \geq r - j - 1$. Noting that $H_T^*(M, M_j) \neq 0$, this shows together with (6.1) that $H_T^*(M, M_j)$ is Cohen-Macaulay of Krull dimension $r - j - 1$.

For the other direction, assume that the sequences (6.2) are exact. By Example 5.6, $H_T^*(M, M_{r-1})$ is a Cohen-Macaulay module of Krull dimension 0. Using $\text{depth } H_T^*(M_j, M_{j-1}) = r - j$, Lemma 5.3 implies that if $H_T^*(M, M_j)$ is a Cohen-Macaulay module of Krull dimension $r - j - 1$, then $\text{depth } H_T^*(M, M_{j-1}) \geq r - j$

and hence (6.1) implies that $H_T^*(M, M_j)$ is Cohen-Macaulay of Krull dimension $r - j$. By induction it follows that $H_T^*(M)$ is Cohen-Macaulay of Krull dimension $r - b$. $\square$

Remark 6.3. If the lowest occurring dimension of a T -orbit is b , then a generic b -dimensional subtorus $K \subset T$ acts locally freely. Choosing another subtorus K' such that $\mathfrak{k} \oplus \mathfrak{k}' = \mathfrak{t}$, we have that K' acts on M/K with fixed points, and $H_T^*(M) \cong H_{K'}^*(M/K)$ as graded rings by the commuting action principle [GuSt 1999, Section 4.6]. Note that M/K is not necessarily a manifold. The T -action on M is Cohen-Macaulay if and only if the K' -action on M/K is equivariantly formal. Note also that the T -action on M and the K' -action on M/K have the same orbit space. With this reduction one can alternatively deduce the theorem above from Theorem 4.4 (respectively a version for more general spaces than differentiable manifolds). Modulo the fact that M/K is not a manifold, also the results in Section 7 and 8 (but not 9 and 10) could be derived similarly. We believe however that is is illuminating to see that the existing proofs can easily be modified from the equivariantly formal to the Cohen-Macaulay setting.

In the case $b = 0$, i.e., $M_b = M_0 = M^t$, the theorem reduces to Theorem 4.4 by Atiyah, Bredon, Franz and Puppe because of

Proposition 6.4. *If the T -action has fixed points, then it is Cohen-Macaulay if and only if it is equivariantly formal.*

Proof. This follows from the graded version of the Auslander-Buchsbaum Theorem [Eis 1995, Exercise 19.8] and the fact that for a graded module over a polynomial ring, the projective dimension is equal to the length of the minimal free resolution [Eis 2004, Corollary 1.8]. $\square$

Note that in the proof of (2) $\Rightarrow$ (1) in Theorem 4.4 by Franz and Puppe [FrPu 2007] this argument is not needed, as they directly show freeness of $H_T^*(M)$.

Examples 6.5. (1) Let T act on M , and denote by K the connected component of the kernel of the action, i.e., of the subgroup of T consisting of the elements that act trivially. Then the T -action on M is Cohen-Macaulay if and only if the T/K -action on M is Cohen-Macaulay.

(2) T -actions with only one local isotropy type are Cohen-Macaulay. The Atiyah-Bredon sequence in this case is $0 \rightarrow H_T^*(M) \rightarrow H_T^*(M) \rightarrow 0$.

(3) Let T act on M effectively and with cohomogeneity one, i.e., the regular orbits have codimension one. There are at most two singular orbits, all of which have codimension two (recall that for us only the local isotropy type is relevant). If the action is locally free, then the action is Cohen-Macaulay by the previous example, so we can assume there exists at least one singular orbit. In this case, the singular orbits have dimension $r - 1$ because the regular orbits are S^1 -fibre bundles over the singular orbits, i.e., $b = r - 1$. To see that the Atiyah-Bredon sequence in this case is exact, we need to show that $H_T^*(M, M_{r-1}) \rightarrow H_T^*(M)$ is the zero map. It is known that the orbit space is homeomorphic to the closed interval $[-1, 1]$, and the orbit space of the regular stratum is either the open interval $(-1, 1)$ or a half-open interval $[-1, 1)$, where the latter case can only occur in the non-orientable case. In any case, $H_T^k(M, M_{r-1}) = H_c^k(M_{reg}/T) = 0$ for $k \neq 1$. But $H_T^1(M) = H^1(M/T) = H^1([-1, 1]) = 0$ by [GGK 2002, Example C.8], which shows that the map in question is the zero map. Thus, cohomogeneity-one actions are Cohen-Macaulay.

The following proposition is a generalization of Corollary 4.3.

Proposition 6.6. *If the action is Cohen-Macaulay, then the bottom stratum of the action equals M_b . More generally, this is true if $H_T^*(M) \rightarrow H_T^*(M_b)$ is injective.*

Proof. Obviously M_b is contained in the bottom stratum. If there is a component N of the bottom stratum not contained in M_b , then $N \cap M_b = \emptyset$. Then, the Thom class of N (with respect to any chosen orientation on the normal bundle) is a nonzero class in $H_T^*(M)$ (because it restricts to the Euler class of N which is nonzero by [Duf 1983, Proposition 3]) that restricts to zero on $H_T^*(M_b)$. $\square$

Proposition 6.7. *If the action is Cohen-Macaulay, then for every T -invariant closed subspace N containing M_{b+1} , we have $H_T^*(N) \cong H_T^*(M) \oplus (\ker H_T^*(N) \rightarrow H_T^*(M_b))$.*

Proof. Because $H_T^*(M) \rightarrow H_T^*(M_b)$ is injective, $H_T^*(M) \rightarrow H_T^*(N)$ is injective as well, and its image does not intersect $\ker H_T^*(N) \rightarrow H_T^*(M_b)$. Exactness of the Atiyah-Bredon sequence at $H_T^*(M_b)$ implies that the image $H_T^*(M) \rightarrow H_T^*(M_b)$ equals the image of $H_T^*(M_{b+1}) \rightarrow H_T^*(M_b)$. Because N is supposed to contain M_{b+1} , this subspace of $H_T^*(M_b)$ is also the same as the image of $H_T^*(N) \rightarrow H_T^*(M_b)$, whence the induced map $H_T^*(M) \rightarrow H_T^*(N)/(\ker H_T^*(N) \rightarrow H_T^*(M_b))$ is an isomorphism. $\square$

The following lemma is obvious.

Lemma 6.8. *Assume the lowest occurring dimension of a T -orbit is the same for every connected component of M . Then the action is Cohen-Macaulay if and only if the action on each connected component is Cohen-Macaulay.*

7. MORSE-BOTT FUNCTIONS

It is well-known that a T -action admitting a Morse-Bott function whose critical set is the fixed point set of the action is equivariantly formal. Replacing the fixed point set by the set of lowest dimensional orbits, we obtain the following generalization of this criterion:

Theorem 7.1. *Assume T acts on a compact manifold M , and let b be the dimension of the smallest occurring orbit. If there exists an invariant Morse-Bott function f whose critical set is equal to a union of connected components of M_b , then the action is Cohen-Macaulay. Moreover, if κ_0 is the absolute minimum of f , then $H_T^*(M) \rightarrow H_T^*(f^{-1}(\kappa_0))$ is surjective.*

Proof. For a real number a , let

$$M^a = f^{-1}((-\infty, a]).$$

Let κ be a critical value of f , and $B_1^\kappa, \dots, B_{j_\kappa}^\kappa$ be the connected components of the critical set at level κ . Denote by $D^-B_i^\kappa$ and $S^-B_i^\kappa$ the disk respectively sphere bundle in the negative normal bundle (see e.g. [AtBo 1982, Section 1]) of B_i^κ . We write λ_i^κ for the rank of $D^-B_i^\kappa$. Let $E_i^\kappa \in H_T^*(B_i^\kappa)$ be the equivariant Euler class of $D^-B_i^\kappa$. Consider the following diagram, in which the top row is the long exact

sequence of the pair $(M^{\kappa+\varepsilon}, M^{\kappa-\varepsilon})$.

$$\begin{array}{ccccccc}
 \cdots & \longrightarrow & H_T^*(M^{\kappa+\varepsilon}, M^{\kappa-\varepsilon}) & \longrightarrow & H_T^*(M^{\kappa+\varepsilon}) & \longrightarrow & H_T^*(M^{\kappa-\varepsilon}) \longrightarrow \cdots \\
 & & \downarrow & & \downarrow & & \\
 & & \bigoplus_i H_T^*(D^- B_i^\kappa, S^- B_i^\kappa) & \longrightarrow & \bigoplus_i H_T^*(D^- B_i^\kappa) & & \\
 & & \downarrow & & \downarrow & & \\
 & & \bigoplus_i H_T^{*- \lambda_i^\kappa}(B_i^\kappa) & \xrightarrow{\bigoplus (\cdot E_i^\kappa)} & \bigoplus_i H_T^*(B_i^\kappa) & &
 \end{array}$$

The two vertical arrows on the left are isomorphisms (one because of excision, and the other is the inverse of the Thom isomorphism), and because $D^- B_i^\kappa$ has no T_i^κ -fixed vectors, where T_i^κ is the isotropy group of B_i^κ , multiplication with the Euler classes is injective by [Duf 1983, Proposition 4]. Thus, $H_T^*(M^{\kappa+\varepsilon}, M^{\kappa-\varepsilon}) \rightarrow H_T^*(M^{\kappa+\varepsilon})$ is injective and we obtain short exact sequences

$$0 \rightarrow H_T^*(M^{\kappa+\varepsilon}, M^{\kappa-\varepsilon}) \rightarrow H_T^*(M^{\kappa+\varepsilon}) \rightarrow H_T^*(M^{\kappa-\varepsilon}) \rightarrow 0.$$

For the absolute minimum κ_0 of f , $H_T^*(M^{\kappa_0})$ is the sum of Cohen-Macaulay modules of Krull dimension $r - b$, and hence Cohen-Macaulay by Lemma 5.4. If for some critical value κ we already know that $H_T^*(M^{\kappa-\varepsilon})$ is Cohen-Macaulay of Krull dimension $r - b$, the short sequence above, combined with Lemma 5.4 and the fact that $H_T^*(M^{\kappa+\varepsilon}, M^{\kappa-\varepsilon})$ is Cohen-Macaulay of Krull dimension $r - b$ as well, implies that $H_T^*(M^{\kappa+\varepsilon})$ is Cohen-Macaulay of the same Krull dimension. $\square$

Remark 7.2. Note that f is automatically an equivariantly perfect Morse-Bott function as all components of M_b are equivariantly self-completing, cf. [AtBo 1984, Prop. 1.9.]

8. EQUIVARIANT DISK BUNDLE DECOMPOSITIONS

In this section, we will prove a generalization of a theorem of Harada, Henriques and Holm, see [HHH 2005], in particular Theorem 2.2 of the unpublished version. For us, a cell bundle is a T -equivariant oriented disk bundle over a compact T -manifold Y . The dimension of a cell bundle is the fiber dimension.

We say that a compact manifold M has a T -invariant disk bundle decomposition if it can be built from a union of zero-dimensional cell bundles, and successively attaching cell bundles. The attaching maps are not required to map the boundary into smaller dimensional cell bundles.

Theorem 8.1. *Let k be a fixed integer. Let M be a compact T -manifold that admits a finite T -invariant disk bundle decomposition into finitely many even-dimensional cell bundles $E \rightarrow Y$ that satisfy the following conditions:*

- (1) *T acts on Y with only one local isotropy type of dimension k*
- (2) *$H_{bas}^{odd}(Y) = H^{odd}(Y/T) = 0$.*

Then the action is Cohen-Macaulay.

Proof. As the maximal dimension of an isotropy algebra is k , we know [FrPu 2003, Proposition 5.1] that the Krull dimension of $H_T^*(M)$ is k .

As in the definition of a disk bundle decomposition, let M^0 be the union of zero-dimensional cell bundles, and M^i be the space obtained by attaching the first i cell bundles. We prove by induction that $H_T^*(M^i)$ is Cohen-Macaulay of Krull dimension k , and $H_T^{odd}(M^i) = 0$. First, $H_T^*(M^0)$ is the sum of Cohen-Macaulay modules

of the form $H_T^*(Y) = H^*(Y/T) \otimes S(\mathfrak{t}_Y^*)$, where $\mathfrak{t}_Y$ is the unique k -dimensional isotropy algebra of Y . So $H_T^*(M^0)$ is Cohen-Macaulay of Krull dimension k by Lemma 5.4, and $H_T^{odd}(M^0) = 0$.

We claim that in the long exact sequence of the pair (M^{i+1}, M^i) , the boundary operator vanishes. For this, it is sufficient to show that $H_T^{odd}(M^{i+1}, M^i) = 0$. Let $E \rightarrow Y$ be the cell bundle that gets attached to M^i . Denote its dimension by $2d$ and the unique isotropy algebra of Y by $\mathfrak{t}_Y$. Then

$$(8.1) \quad H_T^*(M^{i+1}, M^i) = H_T^*(E, \partial E) \stackrel{\text{Thom}}{=} H_T^{*-2d}(Y) = H_{bas}^{*-2d}(Y) \otimes S(\mathfrak{t}_Y^*),$$

so by assumption (2), $H_T^{odd}(M^{i+1}, M^i)$ vanishes. Thus, the boundary operator in the long exact sequence of the pair (M^{i+1}, M^i) vanishes and we obtain a short exact sequence

$$0 \rightarrow H_T^*(M^{i+1}, M^i) \rightarrow H_T^*(M^{i+1}) \rightarrow H_T^*(M^i) \rightarrow 0.$$

It follows that $H_T^{odd}(M^{i+1}) = 0$. Because (8.1) implies that $H_T^*(M^{i+1}, M^i)$ is Cohen-Macaulay of Krull dimension k , $H_T^*(M^{i+1})$ is also Cohen-Macaulay of Krull dimension k by Lemma 5.4. $\square$

9. EQUIVARIANT COHOMOLOGY AND THE BOTTOM STRATUM

Although it is not an equivalent characterization of equivariant formality, the injectivity of the restriction map $H_T^*(M) \rightarrow H_T^*(M^\natural)$ due to the torsion-freeness of $H_T^*(M)$ is an important property of equivariantly formal actions. In this section, we replace $M^\natural$ by the bottom stratum B of the action, and find an algebraic characterization of injectivity of $H_T^*(M) \rightarrow H_T^*(B)$ which has an interesting geometric consequence, see Theorem 9.6. This will be applied in Section 10.

If T acts on a manifold N , then we say that $\alpha \in H_T^*(N)$ is *invisible* if no complexified nonregular isotropy algebra of the T -action on N is contained in $\text{supp } \alpha$. If N is compact, this is by Lemma 3.2 equivalent to saying that for every nonregular isotropy algebra $\mathfrak{k}$ of the action, α is in the kernel of $H_T^*(N) \rightarrow H_T^*(N^\mathfrak{k})$. This motivates the terminology.

Proposition 9.1. *Let T act on a compact manifold M , and let B denote the bottom stratum of the action. Then the natural map*

$$H_T^*(M) \rightarrow H_T^*(B)$$

is injective if and only if for every $p \notin B$, $H_T^(M^p)$ does not contain any invisible element.*

Proof. Assume first that $\alpha \in H_T^*(M^p)$ is invisible for $p \notin B$, i.e., the only complexified isotropy algebra contained in $\text{supp } \alpha$ is $\mathfrak{t}_p \otimes \mathbb{C}$. Because the equivariant push-forward map $H_T^*(M^p) \rightarrow H_T^*(M)$ is injective [Duf 1983, Proposition 4], the image of α has the same support as α and thus maps to zero in $H_T^*(B)$ by Lemma 3.2.

Assume now that for $p \notin B$, $H_T^*(M^p)$ contains no invisible elements. We prove that $H_T^*(M) \rightarrow H_T^*(B)$ is injective by induction over the length s of the longest chain $\mathfrak{t}_1 \subsetneq \mathfrak{t}_2 \subsetneq \dots \subsetneq \mathfrak{t}_s$ of isotropy algebras.

If this length is $s = 1$, i.e., the action has only one local isotropy type, we have $M = B$ and the claim is trivial. Assume the proposition is proven for all actions with $s < m$, and let T act on M with $s = m > 1$.

Let $\mathfrak{k}_j \neq \{0\}$ denote the minimal nonregular isotropy algebras of the action, i.e., if $\mathfrak{h} \subset \mathfrak{k}_j$ is any isotropy group, then either $\mathfrak{h}$ is the regular isotropy group (i.e., $\{0\}$ if the action is effective) or $\mathfrak{h} = \mathfrak{k}_j$. Consider the map

$$\eta : H_T^*(M) \rightarrow \bigoplus_j H_T^*(M^{\mathfrak{k}_j}).$$

By Lemma 3.2, the kernel of η consists of those α whose support does not contain any $\mathfrak{k}_j \otimes \mathbb{C}$. But the $\mathfrak{k}_j$ are exactly the minimal isotropy algebras, so we get

$$\ker \eta = \{\alpha \in H_T^*(M) \mid \alpha \text{ invisible}\}.$$

By assumption (choose a regular p), such invisible elements do not exist, so η is injective. The longest chains of isotropy algebras for the T -actions on $M^{\mathfrak{k}_j}$ are shorter than the one of the action on M , so by induction we know that the maps $H_T^*(M^{\mathfrak{k}_j}) \rightarrow H_T^*(B \cap M^{\mathfrak{k}_j})$, induced by the inclusions, are injective. It follows that

$$H_T^*(M) \rightarrow \bigoplus_j H_T^*(M^{\mathfrak{k}_j}) \rightarrow \bigoplus_j H_T^*(B \cap M^{\mathfrak{k}_j})$$

is injective. But this map consists only of copies of the natural maps induced by the inclusions of components of the bottom stratum, and thus, $H_T^*(M) \rightarrow H_T^*(B)$ has to be injective itself. $\square$

Next, we find a geometric consequence of the existence of an invisible element $\alpha \in H_T^*(M)$. Duflot [Duf 1983, proof of Theorem 1] proves that for every i , the push-forward $(\varphi_i)_* : H_T^*(M_{(i)}) \rightarrow H_T^*(M \setminus M_{i-1})$ of the inclusion $\varphi_i : M_{(i)} \rightarrow M \setminus M_{i-1}$ is injective, i.e., the corresponding Gysin sequence is in fact a short exact sequence

$$(9.1) \quad 0 \rightarrow H_T^*(M_{(i)}) \rightarrow H_T^*(M \setminus M_{i-1}) \rightarrow H_T^*(M \setminus M_i) \rightarrow 0.$$

Note that this is a sequence of $S(\mathfrak{t}^*)$ -modules, see e.g. the discussion on the equivariant push-forward map in [AtBo 1984, §2], or [GGK 2002, p. 221]. These considerations imply the following lemma:

Lemma 9.2. *Let T act on a compact manifold M . If $\alpha \in H_T^*(M)$ is invisible, then α is not in the kernel of the map $H_T^*(M) \rightarrow H_T^*(M_{reg})$.*

Proof. If we can show that an invisible element can never be in the kernel of $H_T^*(M \setminus M_{i-1}) \rightarrow H_T^*(M \setminus M_i)$ for $i < r$, then the claim follows. This kernel is by (9.1) the same as the image of $(\varphi_i)_*$. For any $\omega \in H_T^*(M_{(i)})$, we have $\text{supp}(\varphi_i)_*\omega = \text{supp} \omega$ because of the injectivity of $(\varphi_i)_*$. But on the other hand, if we choose a point p_j in each connected component of $M_{(i)}$, then $H_T^*(M_{(i)}) = \bigoplus_j H_T^*(M_{reg}^{p_j}) = \bigoplus_j H^*(M_{reg}^{p_j}/T) \otimes S(\mathfrak{t}_{p_j}^*)$ by Lemma 3.1, and the $\mathfrak{t}_{p_j}$ are nonregular isotropy algebras on $M \setminus M_{i-1}$. $\square$

Corollary 9.3. *Let T act nontransitively on a connected compact manifold M . If M_{reg}/T is acyclic, i.e., $H_{bas}^*(M_{reg}) = H^*(M_{reg}/T) = \mathbb{R}$, then there are no invisible elements in $H_T^*(M)$.*

Proof. Assume without loss of generality that the T -action is effective. Let $\alpha \in H_T^*(M)$ be invisible. By Lemma 9.2, α defines a nonzero cohomology class in $H_T^*(M_{reg}) = H^*(M_{reg}/T) = \mathbb{R}$, which implies that α is a 0-form. In other words, $1 \in H_T^*(M)$ is invisible. But the support of $1 \in H_T^*(M)$ contains the complexification of every isotropy algebra, cf. Proposition 3.3. This means that the action is locally free, i.e., $M_{reg} = M$. As M_{reg}/T satisfies Poincaré duality, this is only possible if $M_{reg}/T = M/T$ is a point, i.e., the action is transitive. $\square$

Definition 9.4. We call M^p/T a *face* of the orbit space. We say that M/T is *closed-face-acyclic* if its closed faces are acyclic; that means that for any point $p \in M$, we have $H_{bas}^*(M^p) = \mathbb{R}$. If the open faces of M/T are acyclic, i.e., if for all p we have $H_{bas}^*(M_{reg}^p) = \mathbb{R}$, we call M/T *open-face-acyclic*. We say that the orbit space is *almost open-face-acyclic* if we have $H_{bas}^*(M_{reg}^p) = \mathbb{R}$ for all p not contained in the bottom stratum B of the action.

Remark 9.5. For torus manifolds, the notion of face-acyclicity as introduced by [MaPa 2006] is the same as our condition of having closed-face-acyclic orbit space, but note that they use integer coefficients instead of the reals.

With this notation, we obtain

Theorem 9.6. *If M/T is almost open-face-acyclic, then the natural map $H_T^*(M) \rightarrow H_T^*(B)$ is injective.*

Proof. This is just Proposition 9.1, combined with Corollary 9.3 for every M^p . $\square$

10. ACTIONS WITH FACE-ACYCLIC ORBIT SPACE

The goal of this section is to prove that actions with open-face-acyclic orbit space (see Definition 9.4) on orientable compact manifolds are Cohen-Macaulay, see Theorem 10.24. In Subsection 10.1 we investigate the general topological structure of actions with (almost) open-face-acyclic orbit space, such as the dimensions of the strata or the structure of the bottom stratum. In particular, if b is the dimension of the smallest occurring orbit, M_{b+1}/T will be seen to be a connected graph, just as the 1-skeleton of an equivariantly formal action satisfying the GKM conditions, see Subsection 10.2. In Subsections 10.3 and 10.4 we finish the proof that actions with open-face-acyclic orbit space are Cohen-Macaulay, following ideas by Masuda and Panov [MaPa 2006], but with certain differences as mentioned in the introduction. Combined with a statement of Bredon [Bre 1974], our result characterizes equivariantly formal actions on orientable compact manifolds M with $\dim M = 2 \dim T$ via the orbit space, see Subsection 10.5.

10.1. Open- and closed-face-acyclicity. For the following proposition, cf. also the remark after Proposition 9.3 of [MaPa 2006].

Proposition 10.1. *If the orbit space of an effective T -action on an oriented compact manifold M is almost open-face-acyclic, then one of the following statements holds:*

- (1) B is connected.
- (2) *The orbit space is open-face-acyclic, i.e., B consists of finitely many isolated orbits. Moreover, they are all of the same dimension, i.e., there exists b such that $M_b = B$. In addition, M_{b+1} is connected.*

Proof. Assume that B is not connected. In particular, the action is not locally free and hence has at least two local isotropy types.

Let B_0 be a component of B . We have to show that B_0 is an orbit. The components M^p of isotropy manifolds are partially ordered by inclusion, the unique maximal element being M itself. Since the bottom stratum of M is disconnected by assumption, we may choose a minimal such component M^p with the property that the bottom stratum of the T -action on M^p is disconnected, but contains B_0 . Let the other components of the bottom stratum of M^p be denoted by $B_1, \dots, B_s$.

We claim that M_{sing}^p is disconnected. Assume this is not the case, and recall

$$M_{sing}^p = \bigcup_{q \in M^p: \mathfrak{t}_p \neq \mathfrak{t}_q} M^q.$$

For every $q \in M^p$ with $\mathfrak{t}_p \neq \mathfrak{t}_q$, the bottom stratum of the T -action on M^q is connected, and hence one of the B_i , $i = 0, \dots, s$. Further, for two such singular points $q_1, q_2 \in M^p$ such that $M^{q_1} \cap M^{q_2} \neq \emptyset$, their respective bottom strata are, because of connectedness, contained in $M^{q_1} \cap M^{q_2}$ and coincide. Therefore, if we let

$$N_i := \bigcup_{q: \text{the bottom stratum of } M^q \text{ is } B_i} M^q,$$

then $M_{sing}^p = \bigcup_i N_i$ is a disjoint union into nonempty subsets, and hence M_{sing}^p is disconnected.

Consider now the first terms of the long exact sequence in basic cohomology of the pair (M^p, M_{sing}^p) :

$$0 \rightarrow H_{bas}^0(M^p) \rightarrow H_{bas}^0(M_{sing}^p) \rightarrow H_{bas}^1(M^p, M_{sing}^p) \rightarrow \dots$$

It follows that $H_{bas}^1(M^p, M_{sing}^p) \neq 0$. But since $H_{bas}^1(M^p, M_{sing}^p) = H_c^1(M_{reg}^p/T)$, and M_{reg}^p/T satisfies Poincaré duality, the almost open-face-acyclic condition implies that the T -action on M^p has cohomogeneity one. In particular, it has exactly two singular orbits, one of which is B_0 . Because T is a torus, the regular orbits are S^1 -fibre bundles over the singular orbits, and hence the two singular orbits have equal dimension.

It follows that B consists of isolated orbits, and whenever two of those orbits can be joined by a sequence of M^p 's such that the T -action on M^p has cohomogeneity one (we say: they are *linked*), they are of the same dimension. We still need to show that any two of those orbits are linked. If this was not the case, choose an arbitrary component B_0 , and let M^p be minimal with the property that the bottom stratum of M^p has a component linked with B_0 and a component not linked with B_0 . In other words, for all singular $q \in M^p$, the components of the bottom stratum of M^q are either all linked with B_0 or all not linked with B_0 . By an analogous argument as above, M_{sing}^p is disconnected. But this implies that the T -action on M^p has cohomogeneity one, which is a contradiction. $\square$

Example 10.2. An easy example for an action whose orbit space is almost open-face-acyclic but not open-face-acyclic, is the S^1 -action on $M = S^3 = \{(z, w) \mid |z|^2 + |w|^2 = 1\} \subset \mathbb{C}^2$ is given by $t \cdot (z, w) = (tz, w)$. The orbit space M/S^1 is the disk D^2 , and $M^{S^1} = \partial D^2 = S^1$.

For the rest of the section, b will denote the dimension of the smallest occurring orbit.

Lemma 10.3. *Let T act locally freely on a manifold M (e.g. the regular stratum of another T -action) such that $H_{bas}^2(M) = 0$. Then for every $p \in M$, the map in cohomology $H^*(M) \rightarrow H^*(T)$ induced by the orbit map $T \rightarrow M; t \mapsto tp$, is surjective.*

Proof. It suffices to prove that $H^1(M) \rightarrow H^1(T)$ is surjective, as $H^*(T)$ is generated by $H^1(T)$. Fix a basis $X_1, \dots, X_r$ of $\mathfrak{t}$, with dual basis $u_1, \dots, u_r \in \mathfrak{t}^*$. Let $\omega : TM \rightarrow \mathfrak{t}$ be a connection form, i.e., a T -invariant map such that for every $p \in M$, we have $\omega(X_i(p)) = X_i$. Note that a choice of connection form is equivalent to the choice of a T -invariant horizontal distribution, e.g., the orthogonal complement of the orbit with respect to some T -invariant Riemannian metric on M .

We obtain one-forms $\theta_i = u_i \circ \omega$ on M (these are sometimes called connection forms, see e.g. [GuSt 1999, p. 23]). We claim that $d\theta_i$ is a closed basic two-form. The $d\theta_i$ are clearly T -invariant, as ω is T -invariant. Thus,

$$i_{X_j} d\theta_i = di_{X_j}(u_i \circ \omega) = d(u_i(X_j)) = d\delta_{ij} = 0,$$

and hence $d\theta_i$ is a closed basic two-form. By our assumption it follows that the $d\theta_i$ are basic exact, i.e., there exist basic one-forms η_i such that the $\theta_i - \eta_i$ are closed and thus define cohomology classes on M . The pull-back of $\theta_i - \eta_i$ via an orbit map φ_p of a point p is the left-invariant one-form given by u_i since

$$\varphi_p^*(\theta_i - \eta_i)(X_j) = u_i(\omega(d\varphi_p(X_j))) = u_i(X_j) = \delta_{ij}.$$

Since those left-invariant one-forms span $H^1(T)$, the claim follows. $\square$

For $p \in M$, let $d_p = \dim M^p - \dim T \cdot p = \dim M^p/T$. Observe that for $q \in M^p$, we have $d_q \leq d_p$, and if $q \in M_{sing}^p$, even $d_q < d_p$.

Proposition 10.4. *If the orbit space of a T -action on an orientable manifold M is open-face-acyclic, then for all $p \in M_i \setminus M_{i-1}$ we have $d_p = i - b$.*

Proof. The subsequent lemma implies that for every q and p such that $M^q \subset M^p$ and such that there is no $q' \in M^p$ with $M^q \subsetneq M^{q'} \subsetneq M^p$, we have $d_p = d_q + 1$ (apply the lemma to the T/T_p -action on M^p). The claim follows by induction, since for $p \in M_b = B$ it is clear by Proposition 10.1. $\square$

Lemma 10.5. *If the T -action is effective and $H_{bas}^2(M_{reg}) = 0$, then for every $p \in M_{sing}$ such that there is no $q \in M$ with $M^p \subsetneq M^q \subsetneq M$, we have $d_p = \dim M/T - 1$.*

Proof. By Lemma 10.3, the condition on the basic cohomology implies that for any regular point q , the orbit map of q induces a surjective map $H^*(M_{reg}) \rightarrow H^*(T)$. If p is such as in the statement of the lemma, then we can choose ε so small that $N = \exp(S^\varepsilon(\nu M^p)|_{T \cdot p})$, where $S^\varepsilon(\nu M^p)$ is the sphere bundle of radius ε in the normal bundle of M^p , is contained in the regular stratum. We furthermore may assume that $\exp$, restricted to $S^\varepsilon(\nu M^p)|_{T \cdot p}$, is a diffeomorphism onto its image. Then, the map $H^*(M_{reg}) \rightarrow H^*(T)$, induced by the orbit map of some point in N , factors through $H^*(N)$, and we obtain a surjective map $H^*(N) \rightarrow H^*(T)$. On the other hand,

$$S^\varepsilon(\nu M^p)|_{T \cdot p} = T \times_{T_p} S^\varepsilon(\nu_p M^p) = (T \times_{T_p^0} S^\varepsilon(\nu_p M^p))/(T_p/T_p^0).$$

As T_p/T_p^0 is a finite group and we are dealing with $\mathbb{R}$ -coefficients, we have $H^1(N) = H^1(T \times_{T_p^0} S^\varepsilon(\nu_p M^p))^{T_p/T_p^0}$, see e.g. Borel et al. [BBFMP 1960, Cor. III.2.3]. If T' is some complement of the identity component T_p^0 in T , i.e., $T = T_p^0 \times T'$, we have $T \times_{T_p^0} S^\varepsilon(\nu_p M^p) = T' \times S^\varepsilon(\nu_p M^p)$. Since T' is strictly lower dimensional than T , it follows that $H^1(N)$ can only map surjectively onto the r -dimensional space $H^1(T)$ if the sphere $S^\varepsilon(\nu_p M^p)$ and T_p are one-dimensional. But this implies that M^p has codimension two in M , and thus $d_p = \dim M - 2 - \dim T \cdot p = \dim M - \dim T - 1 = \dim M/T - 1$, which finishes the proof. $\square$

Corollary 10.6. *If the orbit space of a T -action on a compact orientable manifold M is open-face-acyclic, then*

- (1) $H_{bas}^k(M_i, M_{i-1}) = 0$ for $k \neq i - b$. The dimension of $H_{bas}^{i-b}(M_i, M_{i-1})$ is equal to the number of components of $M_i \setminus M_{i-1}$.
- (2) For $j < i$, the natural map $H_{bas}^{j-b}(M) \rightarrow H_{bas}^{j-b}(M_i)$ is an isomorphism.
- (3) For $j > i$, $H_{bas}^{j-b}(M_i) = 0$.

Proof. The first part follows from Proposition 10.4 because every M_{reg}^p/T satisfies Poincaré duality. For the second part, write $H_{bas}^{j-b}(M) \rightarrow H_{bas}^{j-b}(M_i)$ as the composition

$$H_{bas}^{j-b}(M) \rightarrow H_{bas}^{j-b}(M_{r-1}) \rightarrow \dots \rightarrow H_{bas}^{j-b}(M_{i+1}) \rightarrow H_{bas}^{j-b}(M_i).$$

Using the exact cohomology sequences of the respective pairs, the first part of the corollary implies that each of those maps is an isomorphism if $j < i$.

The same argument gives that each map in the composition

$$H_{bas}^{j-b}(M_i) \rightarrow H_{bas}^{j-b}(M_{i-1}) \rightarrow \dots \rightarrow H_{bas}^{j-b}(M_b) \rightarrow H_{bas}^{j-b}(M_{b-1}) = 0$$

is an isomorphism if $j > i$, hence the third part follows. $\square$

Corollary 10.7. *If the orbit space of an effective T -action on a compact orientable manifold M is open-face-acyclic, then $\dim M = 2 \dim T - b$.*

Proof. Proposition 10.4 implies $d_p = \dim T - b$ for regular p . Thus, $\dim M = \dim M/T + \dim T = 2 \dim T - b$. $\square$

Corollary 10.8. *If the orbit space of an effective T -action on an orientable compact manifold M is open-face-acyclic, then for all $p \in M$, we have $\dim \nu_p M^p = 2 \dim T_p$. Consequently, the natural T_p -representation on the normal space $\nu_p M^p$ has exactly $\dim T_p$ weights.*

Proof. For $p \in M_i$, we have $\dim T_p = \dim T - i$ and thus $\dim \nu_p M^p = 2 \dim T - b - \dim M^p = 2 \dim T - b - (d_p + i) = 2 \dim T_p$. It follows that the T_p -representation has at most $\dim T_p$ many weights. Because of effectiveness, the second claim follows. $\square$

For any $q \in M^p$, the isotropy representation at q induces T_q -representations on the tangent and normal spaces $T_q M^p$ and $\nu_q M^p$. We have $\nu_q M^q = \nu_q M^p \oplus (\nu_q M^q \cap T_q M^p)$ as T_q -modules. Corollary 10.8 implies that $\nu_q M^p = \bigoplus_{i=1}^{\dim \mathfrak{t}_p} V_{\beta_i}$ and $\nu_q M^q \cap T_q M^p = \bigoplus_{i=1}^{\dim \mathfrak{t}_q - \dim \mathfrak{t}_p} V_{\gamma_i}$, where the V_{β_i} and V_{γ_i} are the weight spaces of the respective weights $\beta_i, \gamma_i \in \mathfrak{t}_q^*$. Because $\mathfrak{t}_p \subset \mathfrak{t}_q$ acts trivially on $\nu_q M^q \cap T_q M^p$, we have $\mathfrak{t}_p = \bigcap_{i=1}^{\dim \mathfrak{t}_q - \dim \mathfrak{t}_p} \ker \gamma_i$. The restriction map $\beta_i \mapsto \beta_i|_{\mathfrak{t}_p}$ is a one-to-one correspondence between the weights of the T_q - and the T_p -representations on $\nu_q M^p$. The weights are constant along M^p in the following sense:

Lemma 10.9. *The weights of the T_p -representation on $\nu_q M^p$, coincide with the weights α_i of the T_p -representation on $\nu_p M^p$. Moreover, the normal bundle νM^p splits equivariantly as $\nu M^p = \bigoplus_{i=1}^k V_{\alpha_i}$.*

Proof. This is essentially Proposition 1 of [Duf 1983], which is an extended version of Proposition 1.6.2 of [Ati 1967] for tori instead of finite groups. $\square$

Proposition 10.10. *If the orbit space of a T -action on an orientable compact manifold M is open-face-acyclic, then it is also closed-face-acyclic, i.e., $H_{bas}^*(M^p) = \mathbb{R}$ for all $p \in M$. In particular, $H_{bas}^*(M) = \mathbb{R}$.*

Proof. We show that the map $M_{reg} \rightarrow M$ induces an isomorphism on basic cohomology by regarding it as the composition $M_{reg} = M \setminus M_{r-1} \rightarrow \dots \rightarrow M \setminus M_b \rightarrow M$. To do this, we have to show that for all i , the map $H_{bas}^*(M \setminus M_{i-1}) \rightarrow H_{bas}^*(M \setminus M_i)$ is an isomorphism. Choose a point p in each connected component of $M_i \setminus M_{i-1}$, together with disjoint neighborhoods U_p of M_{reg}^p that have M_{reg}^p as strong equivariant

deformation retracts, and are diffeomorphic to the normal bundles νM_{reg}^p .

$$\begin{array}{ccccccc}
H_{bas}^*(M \setminus M_{i-1}, M \setminus M_i) & \rightarrow & H_{bas}^*(M \setminus M_{i-1}) & \rightarrow & H_{bas}^*(M \setminus M_i) & \rightarrow & H_{bas}^{*+1}(M \setminus M_{i-1}, M \setminus M_i) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\oplus H_{bas}^*(U_p, U_p \setminus M_{reg}^p) & \rightarrow & \oplus H_{bas}^*(U_p) & \rightarrow & \oplus H_{bas}^*(U_p \setminus M_{reg}^p) & \rightarrow & \oplus H_{bas}^{*+1}(U_p, U_p \setminus M_{reg}^p)
\end{array}$$

In the diagram, the vertical maps on the sides are isomorphisms by excision. Thus, we need to show that the maps $H_{bas}^*(U_p) \rightarrow H_{bas}^*(U_p \setminus M_{reg}^p)$ are isomorphisms, which by our choice of U_p amounts to show that for every $p \in M$, the spaces $(\nu M_{reg}^p)/T$ and $(\nu M_{reg}^p \setminus M_{reg}^p)/T$ are homotopy equivalent.

Let α_i , $i = 1 \dots k$ be the weights of the normal bundle $\nu M_{reg}^p = \bigoplus V_{\alpha_i}$ as in Lemma 10.9. Any vector $v \in \nu_q M_{reg}^p$ can be uniquely written as $v = \sum v_i$, where $v_i \in V_{\alpha_i}(q)$. Because the V_{α_i} are T -invariant, this defines a T -invariant map

$$r : \nu M_{reg}^p \rightarrow \mathbb{R}_{\geq 0}^k; \quad v \mapsto (||v_1||, \dots, ||v_k||).$$

It follows that the map

$$(\nu M_{reg}^p)/T \rightarrow M_{reg}^p/T \times \mathbb{R}_{\geq 0}^k; \quad T \cdot v \mapsto (T \cdot q, r(v))$$

is well-defined. It is clearly surjective, and injectivity follows because the T_q -orbits in $\nu_q M_{reg}^p$ are products of S^1 -orbits in $V_{\alpha_i}(q)$ by Corollary 10.8. Noting that under this map, M_{reg}^p/T corresponds to $M_{reg}^p/T \times \{0\}$, the desired homotopy equivalence follows. $\square$

Proposition 10.11. *If the orbit space of a T -action on an orientable compact manifold M is open-face-acyclic, then the sequence*

$$0 \rightarrow H_{bas}^*(M) \rightarrow H_{bas}^*(M_b) \xrightarrow{\partial_b} H_{bas}^*(M_{b+1}, M_b) \xrightarrow{\partial_{b+1}} \dots \xrightarrow{\partial_{r-1}} H_{bas}^*(M_r, M_{r-1}) \rightarrow 0,$$

where the first map is induced by the inclusion, is exact.

Proof. The proof is the same as the standard proof that the cellular cohomology of a CW complex computes the standard cohomology. Let $\omega \in H_{bas}^{i-b}(M_i, M_{i-1})$ cause nonexactness of the sequence

$$H_{bas}^*(M_b) \xrightarrow{\partial_b} H_{bas}^*(M_{b+1}, M_b) \xrightarrow{\partial_{b+1}} \dots \xrightarrow{\partial_{r-1}} H_{bas}^*(M_r, M_{r-1}) \rightarrow 0$$

at $H_{bas}^{i-b}(M_i, M_{i-1})$ for some $i > b$, i.e., $\partial_i \omega = 0$ but $\omega \notin \text{im } \partial_{i-1}$. Because $\partial_i \omega = 0$, the exact sequence of the triple (M_{i+1}, M_i, M_{i-1}) in basic cohomology implies that there is an element $\eta \in H_{bas}^{i-b}(M_{i+1}, M_{i-1})$ that is mapped to ω under the natural restriction map. We claim that η defines a nontrivial element in $H_{bas}^{i-b}(M_{i+1})$. If that was not the case, η would be in the image of the boundary map $H_{bas}^{i-b-1}(M_{i-1}) \rightarrow H_{bas}^{i-b}(M_{i+1}, M_{i-1})$. But since $H_{bas}^{i-b-1}(M_{i-2}) = 0$ by the third part of Corollary 10.6, this would produce a contradiction to the assumption that $\omega \notin \text{im } \partial_{i-1}$. Thus, $H_{bas}^{i-b}(M_{i+1})$ is nontrivial. By the second part of Corollary 10.6, this implies that $H_{bas}^{i-b}(M) \neq 0$, which is in contradiction to Proposition 10.10.

To finish the proof, either use Proposition 4.5 for basic cohomology, or redo the same argument as above to show that $\ker \partial_b$ is one-dimensional. $\square$

Remark 10.12. This is a version of the Atiyah-Bredon sequence for basic cohomology. Unfortunately, we do not have a proof of the Cohen-Macaulayness of torus actions whose orbit space is open-face-acyclic that makes use of this sequence.

Note that for a general Cohen-Macaulay action, the basic version of the Atiyah-Bredon sequence is not necessarily exact. For example, consider the S^1 -action on

the 4-sphere $M = S^4 = \{(z, w, s) \mid |z|^2 + |w|^2 + s^2 = 1\} \subset \mathbb{C}^2 \times \mathbb{R}$ given by

$$t \cdot (z, w, s) = (tz, tw, s).$$

It has exactly two fixed points and is thus equivariantly formal by criterion (2) listed in Section 4. But the boundary operator $\partial_0 : H_{bas}^*(M^{S^1}) \rightarrow H_{bas}^*(M, M^{S^1})$ is not surjective, as $H_{bas}^3(M, M^{S^1}) = H_c^3(M_{reg}/S^1) \cong H^0(M_{reg}/S^1) = \mathbb{R} \neq 0$.

10.2. The $b + 1$ -skeleton. By the results of Section 10.1 (in particular Propositions 10.1, 10.4, and Corollary 10.8), the $b + 1$ -skeleton M_{b+1} of an action on an orientable compact manifold M with open-face-acyclic orbit space behaves similarly to the one-skeleton of an equivariantly formal action satisfying the so-called GKM conditions (see e.g. [GuSt 1999, Section 11.8]). The only difference is that instead of being composed of two-spheres, M_{b+1} is a union of submanifolds on which T acts with cohomogeneity one. If two such cohomogeneity one submanifolds meet, their intersection consists of either one or two b -dimensional orbits. M_{b+1}/T can be thought of as a graph, with the elements of $M_b/T = B/T$ as vertices. The vertices will be identified with the corresponding b -dimensional orbits, and also with points on that orbit. For $p \in M_b$ we write $[p]$ for Tp , when understood as a vertex. There is one edge for every submanifold M^p with $p \in M_{b+1} \setminus M_b$ connecting its two b -dimensional orbits. Multiple edges between two vertices can occur. This graph is d -valent, with $d = \dim T - b$. Although the orbit space M/T is not necessarily a convex polytope, we will refer to the M^p/T as faces.

Remark 10.13. In view of Remark 6.3, if we choose a b -dimensional subtorus $K \subset T$ acting locally freely, then the T/K -action on M/K satisfies the usual GKM conditions.

Example 10.14. Consider the T^3 -action on $M = S^5 = \{(z_i) \in \mathbb{C}^3 \mid \sum |z_i|^2 = 1\}$ given by $(t_1, t_2, t_3) \cdot (z_1, z_2, z_3) = (t_1 z_1, t_2 z_2, t_3 z_3)$. The bottom stratum M_1 consists of the three one-dimensional orbits, which are circles, and M_2/T^3 is a triangle. The diagonal $S^1 \subset T^3$ acts freely on S^5 , with $S^5/S^1 = \mathbb{C}P^2$. The induced T^2 -action on $\mathbb{C}P^2$ has the same orbit space as the T^3 -action on S^5 .

For every oriented edge $e = M^p/T$, let $i(e)$ denote the initial vertex, $t(e)$ the terminal vertex, and we write $M_e = M^p$. There is a unique weight $\alpha(e) \in \mathfrak{t}_{i(e)}^*$ of the $T_{i(e)}$ -representation on $\nu_{i(e)} Ti(e)$ with kernel $\mathfrak{t}_p$.

Lemma 10.15. *For every two edges e and f with $i(e) = i(f)$, there is a unique edge $\tilde{e}$ with $i(\tilde{e}) = t(f)$ such that $\alpha(e)|_{\mathfrak{t}_f} = \alpha(\tilde{e})|_{\mathfrak{t}_f}$.*

Proof. This is a consequence of Lemma 10.9 and the discussion preceding it. $\square$

10.3. A Chang-Skjelbred Lemma. Although the statements here are more general, most of the arguments in this section are taken from Sections 6 and 7 of [MaPa 2006]. As before, we consider a T -action on an orientable compact manifold M with open-face-acyclic orbit space, and the bottom stratum being the union of the b -dimensional orbits.

For a face $F = M^p/T$, let $\tau_F \in H_T^*(M)$ be the equivariant Thom class of M^p in M with respect to any orientation of the normal bundle, and $E_F \in H_T^*(M^p)$ the equivariant Euler class of the normal bundle of M^p . The restriction of τ_F to M^p is E_F , see e.g. [GGK 2002, p. 221].

Lemma 10.16. *Let $F = M^p/T$ be a face, and $2k$ the codimension of the closed T -invariant submanifold M^p in M . Then for all $q \in M_b \cap M^p$,*

$$E_F|_{T_q} = \prod_{e \not\subset F, i(e)=q} \alpha(e) \in S^k(\mathfrak{t}_q^*) = H_T^{2k}(Tq).$$

For $q \in M_b \setminus M^p$, we have $E_F|_{T_q} = 0$.

Proof. For $q \notin M^p$, the statement is obvious, so let $q \in M_b \cap M^p$. By Lemma 10.9, the normal bundle νM^p splits as the sum of T -equivariant two-plane bundles $\nu M^p = \bigoplus_{e \not\subset F, i(e)=q} V_{\alpha(e)}$. Thus, $E_F = \prod_{e \not\subset F, i(e)=q} E(V_{\alpha(e)})$. The bundle $V_{\alpha(e)}$, restricted to Tq , is

$$V_{\alpha(e)}|_{T_q} = T \times_{T_q} \mathbb{C} = (T'_q \times \mathbb{C})/(T_q/T_q^0)$$

where T'_q is a complement of the identity component T_q^0 in T , i.e., $T = T_q \times T'_q$.

We calculate the Euler class of the T -equivariant bundle $T'_q \times \mathbb{C} \rightarrow T/T_q^0 = T'$ in a way similar to [GGK 2002, Lemma I.3]. See also [BoTu 2001] for the description of the equivariant Euler class in the Cartan model. Note that this bundle is trivial as a T'_q -equivariant bundle. For this, we choose a T -invariant connection form $\Theta \in \Omega^1(T'_q \times S^1)^T$ such that the T'_q -orbits are horizontal. Denoting the natural projection $T' \rightarrow Tq$ by ρ , one shows as in Lemma I.3 of the reference above that

$$\rho^*(E_F)(\xi) = E(T'_q \times \mathbb{C})(\xi) = d_T \Theta(\xi) = \alpha(e)(\pi_{\mathfrak{t}_q}(\xi))$$

for all $\xi \in \mathfrak{t}$, where $\pi_{\mathfrak{t}_q} : \mathfrak{t} \rightarrow \mathfrak{t}_q$ is the projection along the decomposition $\mathfrak{t} = \mathfrak{t}_q \oplus \mathfrak{t}'_q$. The form part vanishes because the curvature of Θ is zero by choice of Θ . Using the isomorphism $\rho^* : S(\mathfrak{t}'_q) \cong H_T^*(Tq) \rightarrow H_T^*(T/T_q^0)$, the claim follows. $\square$

Note that because of the lemma, the restricted Euler class $E_F|_{T_q}$ is independent of the chosen orientation of the normal bundle.

The next lemmas are analogous to Lemma 6.2 and 7.3 of [MaPa 2006]; the only difference is that we are not allowed to subtract the restrictions of equivariant differential forms to different components of the bottom stratum.

Lemma 10.17. *Let N be a closed invariant subspace of M containing M_{b+1} , and $\omega \in H_T^*(N)$. Choose an edge e and write $[p] = i(e)$ and $[q] = t(e)$. Then the polynomials $\omega|_{Tp} \in S(\mathfrak{t}_p^*) = H_T^*(Tp)$ and $\omega|_{Tq} \in S(\mathfrak{t}_q^*) = H_T^*(Tq)$ coincide on the intersection $\mathfrak{t}_e = \mathfrak{t}_p \cap \mathfrak{t}_q$, where $\mathfrak{t}_e$ is the isotropy algebra of M_e .*

Proof. Using Lemma 3.1, we obtain the following diagram, in which the upper right space is nothing but $S(\mathfrak{t}_p^*) \oplus S(\mathfrak{t}_q^*)$.

$$\begin{array}{ccccccc} H_T^*(M) & \longrightarrow & H_T^*(Tp) \oplus H_T^*(Tq) & \xrightarrow{\cong} & (H_{T/T_e}^*(Tp) \otimes S(\mathfrak{t}_e^*)) \oplus (H_{T/T_e}^*(Tq) \otimes S(\mathfrak{t}_e^*)) \\ \downarrow & & \downarrow & & \downarrow \\ H_{T_e}^*(M_e) & \rightarrow & H_{T_e}^*(Tp) \oplus H_{T_e}^*(Tq) & \xrightarrow{\cong} & (H^*(Tp) \otimes S(\mathfrak{t}_e^*)) \oplus (H^*(Tq) \otimes S(\mathfrak{t}_e^*)) \end{array}$$

Since the diagram commutes and $H_{T_e}^*(M_e) = H^*(M_e) \otimes S(\mathfrak{t}_e^*)$, we see that the image of ω in the bottom right space is of the form $(\sum_i \omega_i|_{Tp} \otimes f_i, \sum_i \omega_i|_{Tq} \otimes f_i)$ for some $f_i \in S(\mathfrak{t}_e^*)$ and $\omega_i \in H^*(M_e)$. As the restrictions of $\omega|_{Tp}$ and $\omega|_{Tq}$ to $S(\mathfrak{t}_e^*)$ are given by those summands for which ω_i is a 0-form, the lemma follows. $\square$

Let F be a face of M/T , and $[q] \in F$ a vertex of F . We denote by $I(F)_{[q]} \subset S(\mathfrak{t}_q^*)$ the ideal generated by all $\alpha(e)$ with $e \subset F$.

Lemma 10.18. *Let N be a closed invariant subspace of M containing M_{b+1} , and let F be a face of M/T . For every $\omega \in H_T^*(N)$, if $\omega|_{T_p} \notin I(F)_{[p]}$ for some vertex $[p] \in F$, then $\omega|_{T_q} \notin I(F)_{[q]}$ for every vertex $[q] \in F$.*

Proof. Suppose $\omega|_{T_q} \in I(F)_{[q]}$ for some vertex $[q] \in F$, i.e.

$$\omega|_{T_q} = \sum_{e \subset F: i(e)=[q]} \alpha(e)g_e$$

for some $g_e \in S(\mathfrak{t}_q^*)$. Now choose another vertex $[\tilde{q}]$ that is joined to $[q]$ by an edge f . By Lemma 10.15, for every e in the sum above there is a unique edge $\tilde{e} \subset F$ with $i(\tilde{e}) = [\tilde{q}]$ such that $\alpha(\tilde{e})|_{\mathfrak{t}_f} = \alpha(e)|_{\mathfrak{t}_f}$. If we define

$$\eta := \sum_e \alpha(\tilde{e})g_{\tilde{e}} \in I(F)_{[\tilde{q}]}$$

where $g_{\tilde{e}} \in S(\mathfrak{t}_{\tilde{q}})$ is any polynomial with $g_{\tilde{e}}|_{\mathfrak{t}_f} = g_e|_{\mathfrak{t}_f}$, then Lemma 10.17 implies that $\omega|_{T_{\tilde{q}}} - \eta \in S(\mathfrak{t}_{\tilde{q}}^*)$ vanishes on $\mathfrak{t}_f$. In particular it is divisible by the weight that vanishes on $\mathfrak{t}_f$, and hence $\omega|_{T_{\tilde{q}}} \in I(F)_{[\tilde{q}]}$.

This completes the proof because the $b+1$ -skeleton of F is connected by Proposition 10.1. $\square$

For every closed invariant subspace $N \subset M$ containing M_{b+1} , define

$$K_N = \ker(H_T^*(N) \rightarrow H_T^*(M_b)).$$

For $b = 0$, i.e., the bottom stratum $M_b = M_0$ being the fixed point set, K_N is the torsion submodule of $H_T^*(N)$.

Proposition 10.19. *For every closed invariant subspace $N \subset M$ containing M_{b+1} , the quotient $H_T^*(N)/K_N$ is generated by the restrictions of the elements τ_F to N .*

Proof. Now that we have transferred the necessary Lemmata 10.16 and 10.18 to our situation, the proof is exactly the same as the proof of Proposition 7.4 in [MaPa 2006], and we therefore omit it. It does not complicate things to consider N instead of the whole manifold M , but note that it is important that N contains the whole $(b+1)$ -skeleton. $\square$

As a corollary we obtain a version of the Chang-Skjelbred Lemma for actions with open-face-acyclic orbit space, compare [ChSk 1974, Lemma 2.3].

Corollary 10.20. (1) *For every closed invariant subspace $N \subset M$ containing M_{b+1} , we have $H_T^*(N) = (\text{im } H_T^*(M) \rightarrow H_T^*(N)) \oplus K_N = H_T^*(M) \oplus K_N$ as $S(\mathfrak{t}^*)$ -modules.*

(2) *The sequence*

$$0 \rightarrow H_T^*(M) \rightarrow H_T^*(M_b) \rightarrow H_T^*(M_{b+1}, M_b)$$

is exact.

Proof. Because $H_T^*(M) \rightarrow H_T^*(M_b)$ is injective by Theorem 9.6, the image of $H_T^*(M) \rightarrow H_T^*(N)$ does not intersect K_N . That the two submodules span $H_T^*(N)$ follows directly from Proposition 10.19.

To prove (2), note that exactness at $H_T^*(M)$ was proven in Theorem 9.6. Taking $N = M_{b+1}$ in (1), we see that $\text{im } H_T^*(M) \rightarrow H_T^*(M_b) = \text{im } H_T^*(M_{b+1}) \rightarrow H_T^*(M_b)$, which is exactness at $H_T^*(M_b)$. $\square$

10.4. Actions with open-face-acyclic orbit space are Cohen-Macaulay. Masuda and Panov [MaPa 2006, Definition 5.3] define the *face ring* of M/T as the graded ring

$$\mathbb{R}[M/T] = \mathbb{R}[\tau_F \mid F \text{ a face of } M/T]/I,$$

where I is the ideal generated by elements of the form

$$\tau_F \tau_G - \tau_{F \vee G} \cdot \sum_{E \in F \cap G} \tau_E.$$

Here, in case F and G have nonempty intersection, $F \vee G$ is the unique smallest face containing F and G , and zero otherwise. The notation $E \in F \cap G$ means that E is a connected component of $F \cap G$. One proves just as in [MaPa 2006, Section 6] that the canonical (after fixing compatible orientations on all normal bundles) homomorphism $\mathbb{R}[M/T] \rightarrow H_T^*(M)$ is well-defined and injective, and by Proposition 10.19 and Theorem 9.6 it is surjective as well. Note that because we have already proven injectivity of $H_T^*(M) \rightarrow H_T^*(M_b)$, we can work with $H_T^*(M)$ itself instead of $H_T^*(M)/(\ker H_T^*(M) \rightarrow H_T^*(M_b))$.

Example 10.21. Consider the T^3 -action on $S^5 = \{(z_i) \mid \sum |z_i|^2 = 1\} \subset \mathbb{C}^3$ defined by $(t_1, t_2, t_3) \cdot (z_1, z_2, z_3) = (t_1 z_1, t_2 z_2, t_3 z_3)$ and the T^2 -action on $\mathbb{C}P^2$ defined by $(t_1, t_2) \cdot [z_0 : z_1 : z_2] = [z_0 : t_1 z_1 : t_2 z_2]$. These actions are Cohen-Macaulay (the latter even equivariantly formal) and their orbit spaces coincide and are open-face-acyclic. Hence the equivariant cohomologies $H_{T^3}^*(S^5)$ and $H_{T^2}^*(\mathbb{C}P^2)$ are isomorphic as rings. Alternatively, this follows from Remark 6.3 as the diagonal circle S^1 in T^3 acts freely on S^5 such that the induced T^2 -action on $S^5/S^1 = \mathbb{C}P^2$ coincides with the action described above.

Lemma 10.22. *If $F = M^p/T$ is a face such that for every subface $G \subset F$, any intersection of a face H with G is connected, then $H_T^*(M) \rightarrow H_T^*(M^p)$ is surjective.*

Proof. By Proposition 10.19 and Theorem 9.6, $H_T^*(M^p)$ is generated by the Thom classes of faces in M^p . Let τ_G be such a Thom class, with $G = M^q/T \subset F$. There is a unique maximal face $H = M^{\tilde{q}}/T$ in M/T whose intersection with F is G . For a T -invariant metric on M , we have that the normal bundle of $M^{\tilde{q}}$ in M , restricted to M^q , coincides with the normal bundle of M^q in M^p . Thus, $\tau_H \in H_T^*(M)$ is mapped onto $\tau_G \in H_T^*(M^p)$. $\square$

Remark 10.23. The condition on F is necessary. For example, consider the action of a two-dimensional maximal torus $T \subset \mathrm{SO}(5)$ on $M = S^4$. If $K \subset T$ is a one-dimensional stabilizer, then $H_T^*(M) \rightarrow H_T^*(M^{\mathfrak{k}})$ is not surjective. In fact, $\dim H_T^2(M) = 2$, but $\dim H_T^2(M^{\mathfrak{k}}) = 3$.

Theorem 10.24. *Every torus action on a compact orientable manifold with open-face-acyclic orbit space is Cohen-Macaulay.*

Proof. We prove the theorem by induction on the dimension of the orbit space. As in [MaPa 2006, Theorem 9.3] we blow up faces of M/T (i.e., we replace submanifolds M^p by the complex projectivizations of the respective normal bundles $P(\nu M^p)$, see [MaPa 2006, Section 9] or [MMP 2007, Section 8]) successively until we arrive at a T -manifold $\widehat{M}$ whose orbit space satisfies that the intersection of any two faces of $\widehat{M}/T$ is connected (i.e., empty or a face). In order to be able to apply Lemma 10.22, we need to choose the faces to be blown up such that the assumptions for the lemma are satisfied. More precisely, let

$$\mathcal{F}(M) = \{F \mid F \text{ a face of } M/T \text{ such that for all faces } G, F \cap G \text{ is connected}\}.$$

It is clear that $\mathcal{F}(M)$ contains all vertices. If there are edges not contained in $\mathcal{F}(M)$, we can at first blow up along vertices until we obtain M' such that all edges of M'/T are in $\mathcal{F}(M')$. Continuing this process with the higher-dimensional faces, we obtain a sequence of T -manifolds N_i with collapse maps

$$\widehat{M} = N_k \rightarrow N_{k-1} \rightarrow \dots \rightarrow N_1 \rightarrow N_0 = M$$

such that N_{i+1} is obtained from N_i by blowing up a face $F_i = N_i^{p_i}/T \in \mathcal{F}(N_i)$. Note that because $F_i \in \mathcal{F}(N_i)$, every subface of the new facet $P(\nu N_i^{p_i})/T$ is in $\mathcal{F}(N_{i+1})$.

$H_T^*(\widehat{M})$ is a $*$ local positively graded ring, with $*$ maximal ideal generated by the homogeneous elements of positive degree. Lemma 8.2. of [MaPa 2006] implies that $\mathbb{R}[\widehat{M}/T] = H_T^*(\widehat{M})$ is Cohen-Macaulay as $*$ local graded ring. Considering $H_T^*(\widehat{M})$ as a module over itself, a graded version of [Ser 2000, Prop. IV.12] implies that it is also Cohen-Macaulay as an $S(\mathfrak{t}^*)$ -module. Its Krull dimension is $r - b$, as the maximal dimension of an isotropy algebra of $\widehat{M}$ is $r - b$. It remains to show that if the action on the blown-up manifold is Cohen-Macaulay, then so is the original one.

Assume we have already shown that $H_T^*(N_{i+1})$ is Cohen-Macaulay of Krull dimension $r - b$; we show it for $H_T^*(N_i)$.

$$\begin{array}{ccccccc} 0 & \longrightarrow & H_T^*(N_i, N_i^{p_i}) & \longrightarrow & H_T^*(N_i) & \longrightarrow & H_T^*(N_i^{p_i}) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \rightarrow & H_T^*(N_{i+1}, P(\nu N_i^{p_i})) & \rightarrow & H_T^*(N_{i+1}) & \rightarrow & H_T^*(P(\nu N_i^{p_i})) \rightarrow 0 \end{array}$$

By Lemma 10.22 and the observations above, the lower horizontal sequence is exact. The left vertical map is an isomorphism, and hence the upper horizontal sequence is exact as well. We know that $H_T^*(N_{i+1})$ is Cohen-Macaulay, and $H_T^*(N_i^{p_i})$ and $H_T^*(P(\nu N_i^{p_i}))$ are Cohen-Macaulay by induction. Since all Krull dimensions are equal, it follows that $H_T^*(N_{i+1}, P(\nu N_i^{p_i})) = H_T^*(N_i, N_i^{p_i})$ is either the zero module or Cohen-Macaulay of Krull dimension $r - b$ by the second statement of Lemma 5.4, and then the first statement of Lemma 5.4 implies that $H_T^*(N_i)$ is Cohen-Macaulay of the same Krull dimension. $\square$

10.5. The equivariantly formal case. For $b = 0$, i.e., $\dim M = 2 \dim T$, the converse of Theorem 10.24 was proven by Bredon, see [Bre 1974, Corollary 3]. We thus have

Theorem 10.25. *An effective T -action on an orientable compact manifold M with $\dim M = 2 \dim T$ is equivariantly formal if and only if its orbit space is open-face-acyclic.*

Still in the case $\dim M = 2 \dim T$, there is a relation between the number of connected components of $M_i \setminus M_{i-1}$ and the Betti numbers of M . For an arbitrary T -action on a compact manifold M , Duflot calculated the Poincaré series of $H_T^*(M)$ in terms of the components of $M_i \setminus M_{i-1}$. Letting λ_i denote the number of connected components of $M_i \setminus M_{i-1}$, her result simplifies in the case of an action with open-face-acyclic orbit space to the following

Proposition 10.26 ([Duf 1983, Theorem 2]). *For a T -action with open-face-acyclic orbit space, the Poincaré series of $H_T^*(M)$ is given by $\sum_{i=b}^r \lambda_i \left(\frac{t^2}{1-t^2} \right)^{r-i}$.*

Note that her notation is slightly different from ours: she indexes the M_i by the dimensions of the isotropy groups, not the dimensions of the orbits. Using

the isomorphism between $H_T^*(M)$ and the face ring of M/T , Masuda and Panov [MaPa 2006, Theorem 5.12, Theorem 7.7] obtain the same equation for torus manifolds with $H^{odd}(M, \mathbb{Z}) = 0$ using the fact that the Poincaré series of the face ring was determined in [Sta 1991, Proposition 3.8]. However, Proposition 10.26 follows independently from this isomorphism, as we only combine our calculation of the codimensions of the M^p in Corollary 10.8 with Theorem 2 of [Duf 1983].

On the other hand, if T acts on an orientable compact manifold M with open-face-acyclic orbit space and $\dim M = 2 \dim T = 2r$, the action is equivariantly formal by Theorem 10.25. Thus, we know that in this case $H_T^*(M) = H^*(M) \otimes S(\mathfrak{t}^*)$ as a graded $S(\mathfrak{t}^*)$ -module, and hence the Poincaré series of $H_T^*(M)$ is given by $\frac{\sum_i b_{2i} t^{2i}}{(1-t^2)^r}$, where $b_i = \dim H^i(M)$ (note that the odd Betti numbers vanish since $H_T^*(M)$ maps injectively into $H_T^*(M^T)$, and the fixed point set consists of isolated points). Equating these two expressions for the Poincaré series, we obtain that the λ_i determine the b_i and vice versa:

Proposition 10.27. *For a T -action on an orientable compact manifold M with open-face-acyclic orbit space and $\dim M = 2 \dim T$, we have*

$$b_{2i} = b_{2(r-i)} = \sum_{j=i}^r (-1)^{j-i} \binom{j}{i} \lambda_j.$$

For an arbitrary equivariantly formal action, Bredon related the Poincaré series of M with the Poincaré series of the (compact cohomology of the) components of $M_i \setminus M_{i-1}$ using the Atiyah-Bredon sequence, see the equation on the bottom of p. 846 in [Bre 1974]. For a T -action with open-face-acyclic orbit space, his equation simplifies to Proposition 10.27. Note that, using Poincaré duality for M and the components of $(M_i \setminus M_{i-1})/T$, one can see that in the case of an equivariantly formal action on an orientable compact manifold, Theorem 2 of [Duf 1983] is the same as the equation by Bredon.

Example 10.28. Consider the following T^3 -actions on the 6-dimensional manifolds $S^4 \times S^2$ and $\mathbb{C}P^3$: on $S^4 \times S^2$, we regard the action given by the product of the T^2 -action on $S^4 = \{(z, w, s) \mid |z|^2 + |w|^2 + s^2 = 1\} \subset \mathbb{C}^2 \times \mathbb{R}$ defined by

$$(t_1, t_2) \cdot (z, w, s) = (t_1 z, t_2 w, s)$$

and the standard S^1 -action on S^2 . On $\mathbb{C}P^3$ we have the T^3 -action given by

$$(t_1, t_2, t_3) \cdot [z_0 : z_1 : z_2 : z_3] = [z_0 : t_1 z_1 : t_2 z_2 : t_3 z_3].$$

Both these actions are equivariantly formal (e.g. because they have exactly 4 fixed points, or because $H^{odd}(M) = 0$ in both cases) and have open-face-acyclic orbit space. As the cohomologies of $\mathbb{C}P^3$ and $S^4 \times S^2$ are isomorphic as graded vector spaces, the numbers of connected components λ_i of $M_i \setminus M_{i-1}$ have to coincide for these actions. In fact, they are $\lambda_0 = 4$, $\lambda_1 = 6$, $\lambda_2 = 4$ and $\lambda_3 = 1$. For $\mathbb{C}P^3$, the orbit space is a tetrahedron, whereas for $S^4 \times S^2$ it is a cylinder, see Figure 1. In the pictures, the dots represent the fixed points. Note that whereas the equivariant cohomologies $H_{T^3}^*(\mathbb{C}P^3)$ and $H_{T^3}^*(S^4 \times S^2)$ are isomorphic as graded $S(\mathfrak{t}^*)$ -modules, their multiplicative structures do not coincide. In fact, the face rings of the tetrahedron and the cylinder are not isomorphic (e.g. in the face ring of the cylinder the product of the Thom classes of the top and the bottom face is zero, whereas in the face ring of the tetrahedron two elements of degree two whose product is zero are linearly dependent).

FIGURE 1. Orbit spaces occurring in Example 10.28.

Note that the tetrahedron also appears as the orbit space of e.g. the T^4 -action on $S^7 = \{(z_i) \mid \sum |z_i|^2 = 1\} \subset \mathbb{C}^4$ given by

$$(t_1, t_2, t_3, t_4) \cdot (z_1, z_2, z_3, z_4) = (t_1 z_1, t_2 z_2, t_3 z_3, t_4 z_4),$$

with the vertices corresponding to the one-dimensional orbits. By Theorem 10.24, this action is Cohen-Macaulay, with $H_{T^4}^*(S^7)$ of Krull dimension 3. In fact, $H_{T^4}^*(S^7)$ is isomorphic to $H_{T^3}^*(\mathbb{C}P^3)$ as a ring. In view of Remark 6.3, this is clear as the diagonal circle S^1 in T^4 acts freely on S^7 such that the induced T^3 -action on $S^7/S^1 = \mathbb{C}P^3$ is the action described above.
